Interoperability Process Reference Manual (IPRM)

84 1.0 Introduction

85 One of the major issues facing the Smart Grid community to-date is unacceptable levels of product
86 interoperability with products claiming to be certified to common standards-based communication
87 technologies. This poor level of product interoperability formed the basis in which the Smart Grid
88 Testing and Certification Committee (SGTCC) was tasked by the Smart Grid Interoperability Panel
89 (SGIP) to create “the necessary documentation and organizational framework for compliance, in-
90 teroperability and cyber security testing and certification”. The SGTCC determined that an Interop-
91 erability Process Reference Manual (IPRM) was a critical part of this framework.

92

93 The IPRM outlines the conformance, interoperability and cyber-security testing and certification
94 requirements for SGIP-recommended Smart Grid standards. This document has been designed to
95 capture testing and certification processes and best practices needed to verify product interopera-
96 bility amongst two or more products using the same standards-based communications technology.
97 These processes and best practices are intended for use by an Interoperability Testing and Certifi-
98 cation Authority (ITCA) in the design and management of a testing and certification program.

99

100 This IPRM focuses on describing the functions and responsibilities of the ITCA, but does not pro-
101 pose an organizational structure since it will vary based on the standard and standard's market-
102 place.

Interoperability Process Reference Manual (IPRM)

103 2.0 Purpose

104 The IPRM outlines the role of an ITCA and specifies the testing and certification processes associ-
105 ated with achieving interoperability for a specific smart grid standard. The IPRM is intended for
106 adoption by any ITCA that is responsible for coordinating testing and certification of a Smart Grid
107 technology standard. Mandatory requirements are denoted by the keyword “shall”, and other rec-
108 ommended best practices are denoted with keywords “should, must or may”.

109
110 In the context of interoperability, product certification is intended to provide high confidence that a
111 product, when integrated and operated within the Smart Grid, will function as stated under specific
112 business conditions and / or criteria. The IPRM defines criteria, recommendations and guidelines
113 for product interoperability and conformance certification. It is important to understand “Interopera-
114 bility” has no meaning for a single product but for a relationship among two or more products. Al-
115 ternatively, conformance does have meaning for one product as it applies to its meeting the re-
116 quirements of the standard or test profile. Conformance testing alone does not guarantee interoper-
117 erable products and interoperability testing does not necessarily mean that products are confor-
118 mant to the standard. Conformance testing increases the likelihood that products will be interoper-
119 able and is typically a pre-cursor to interoperability testing. The IPRM requires that a certified in-
120 teroperable product shall conform to a standard or profile of the standard.

121

Interoperability Process Reference Manual (IPRM)

122 3.0 Intended Audience

123 The IPRM is to be used by the ITCA in its role in managing the interoperability testing and certifica-
124 tion processes of smart grid standards based products. While standards-based products can
125 reach the market-place and eventually be interoperable, many standards require organizations
126 whose sole function is to drive and coordinate adoption from a business and marketing point of
127 view. The function of the ITCA is to increase the adoption rate by bringing together end-users,
128 vendors, test labs and certification bodies with the goal of reducing lead times associated with
129 standards development and the subsequent provision of interoperable products in the market-
130 place.

131

132 While the IPRM's audience is the ITCA, it recognizes that many parties will actively participate in
133 the generic product interoperability certification processes. In particular, the following major actors
134 are involved with the evolution of interoperable standards based technologies:

- 135 • Product and System Integrators
- 136 • Product Developers and Vendors
- 137 • SSOs - developing interoperability standards
- 138 • Interoperability Testing and Certification Authority
- 139 • Testing Laboratories
- 140 • Certification Bodies
- 141 • Customers/users of the products

Interoperability Process Reference Manual (IPRM)

142 4.0 Scope

143

144 The IPRM assumes an ITCA is established for a given standard and addresses responsibilities of
145 that ITCA. Some activities associated with ITCA include:

- 146 • Designing, developing and managing a testing and certification program
- 147 • Monitoring and enforcing testing and certification policies and procedures
- 148 • Managing relationships between various actors and stakeholders
- 149 • Managing conformance and interoperability assessments in the course of standard crea-
150 tion

151 It should be noted that ITCAs do not currently exist for all Smart Grid interoperability standards. As
152 a result, new ones will need to be organized to coordinate and help drive adoption of specific stan-
153 dards. While the IPRM can help new ITCAs in establishing their policies and best practices, it does
154 not address the process by which an ITCA is formed.

Interoperability Process Reference Manual (IPRM)

155 5.0 Overview

156

157 The overview provided in this section will assist in clarifying the goals and requirements of the Inter-
158 operability Process Reference Manual (IPRM).

159

160 5.1 IPRM Model for Product Testing and Certification

161 The testing of products involves the transformation of use-case scenarios into an appropri-
162 ate set of testing scenarios. Figure 1 depicts the process of transforming product use
163 cases into a set of test scenarios which will be used to define an application test profile
164 group¹. A product vendor instantiates the application test profile group by building a par-
165 ticular hardware or software solution. As a rule, product vendors attest to the supported
166 feature set by way of the proforma (e.g. protocol and / or profile) implementation confor-
167 mance statement (PICS)². PICS documents, together with the test specification and the
168 most up-to-date applicable tests as maintained on the Test Case Reference List (TCRL)²,
169 produce a Test Plan for a particular testing campaign².

¹ Application test profile group is the set of test profile categories (the folders in the picture) that form the totality of a series of tests that correspond to verification of the application profile feature set.

Interoperability Process Reference Manual (IPRM)

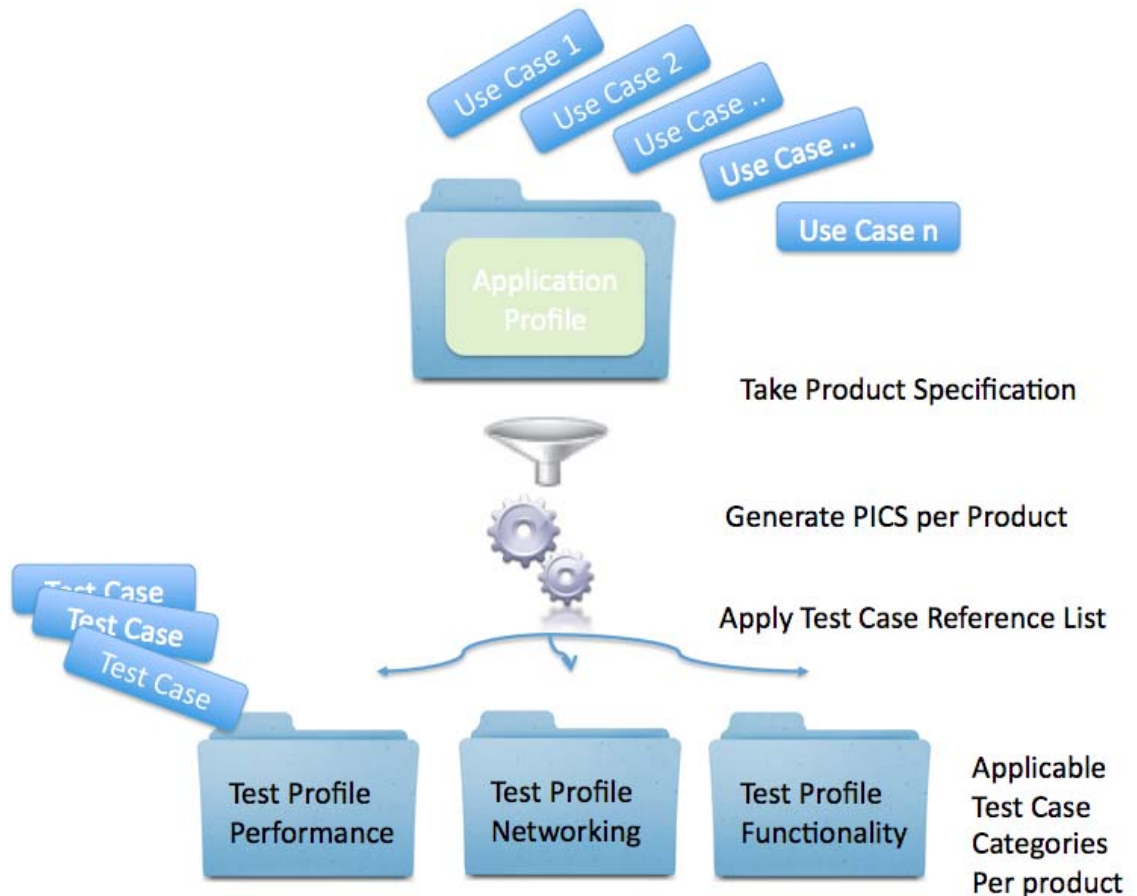

Figure 1 – Use Case to Test Case Transformation

170

171

172

173

The application test profile group is used to develop test plans with the intent of directing a test laboratory in executing the appropriate product tests within each of the test profile categories. A set of conformance tests is generally required during the testing process, and applies to different layers of a product.

177

178

In Figure 2, the 7-layer Open Systems Interconnection (OSI) model illustrates the communication network environment for a product. Generally, both hardware and software products fit into this communication application architecture model and their specific test profiles

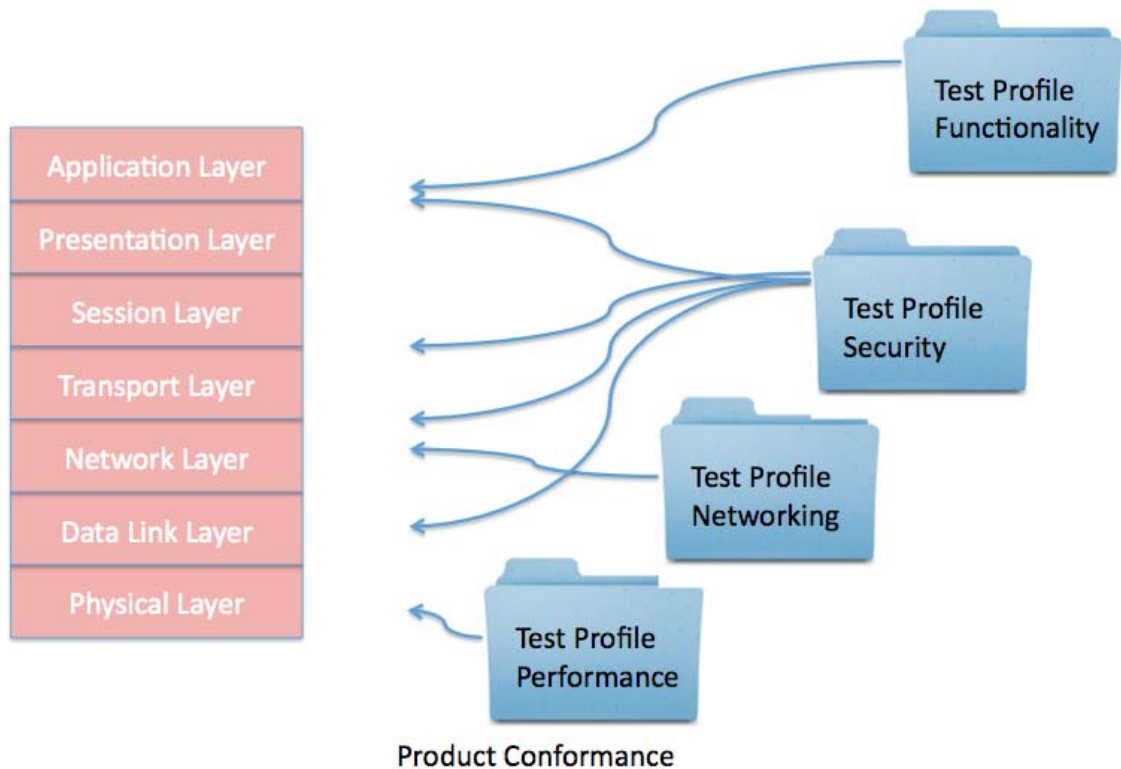

179

180

Interoperability Process Reference Manual (IPRM)

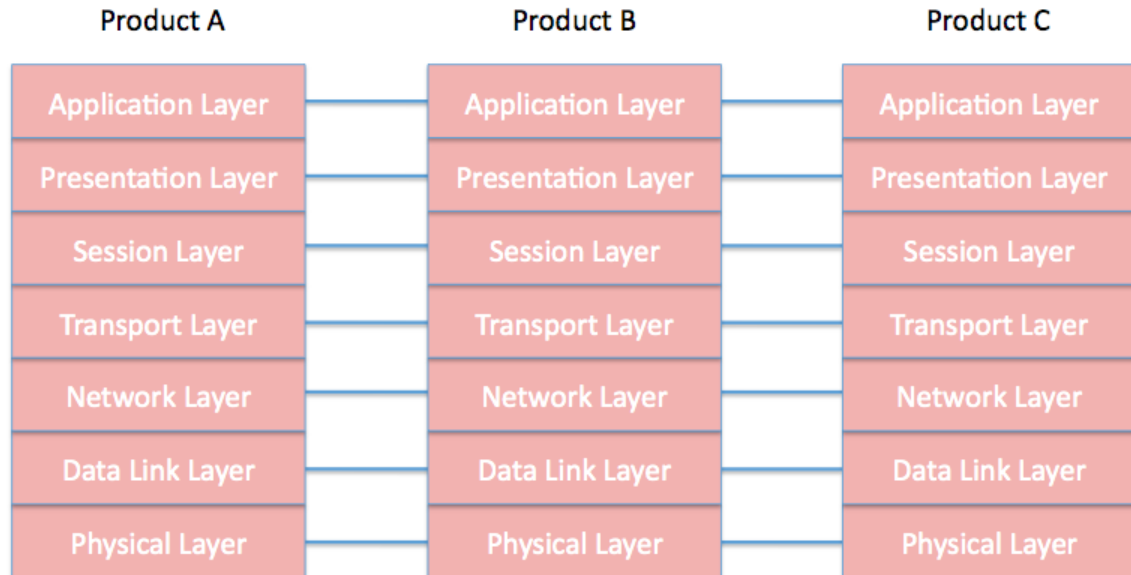

181 relate directly to a respective layer of the OSI model. Each specific test profile will generally
182 use a test setup or "test harness²". It is the role of the ITCA to determine the technical vi-
183 ability of using test harnesses for the product interoperability testing processes.
184

185
186 **Figure 2 – 7 Layer OSI Model Mapped To Product Testing Profiles**
187 Prior to interoperability testing, a product is tested for conformance to the specification at
188 each relevant OSI layer.
189

Interoperability Process Reference Manual (IPRM)

Product Interoperability

190

191

Figure 3 – Product Interoperability Correlations At Each Relevant OSI Layer

192

193

As depicted in Figure 3, product interoperability testing involves hardware and / or software products (e.g. product A, B and C) intercommunicating at each relevant OSI layer. With this depiction, product A may be part of a validated test harness and therefore treated as a “golden unit”. The introduction of golden units (i.e. actual production market devices) in a testing program is made at the discretion of the ITCA. In general, product conformance testing assures product level interoperability.

197

198

199

200

The set of conformance and product interoperability tests help define a testing program for smart grid solutions, and is applicable to both hardware and software products. A typical set-up in the communication industry is the alignment of a testing program with the specific test profiles. As noted previously conformance testing is in general “orthogonal”, or sepa-

201

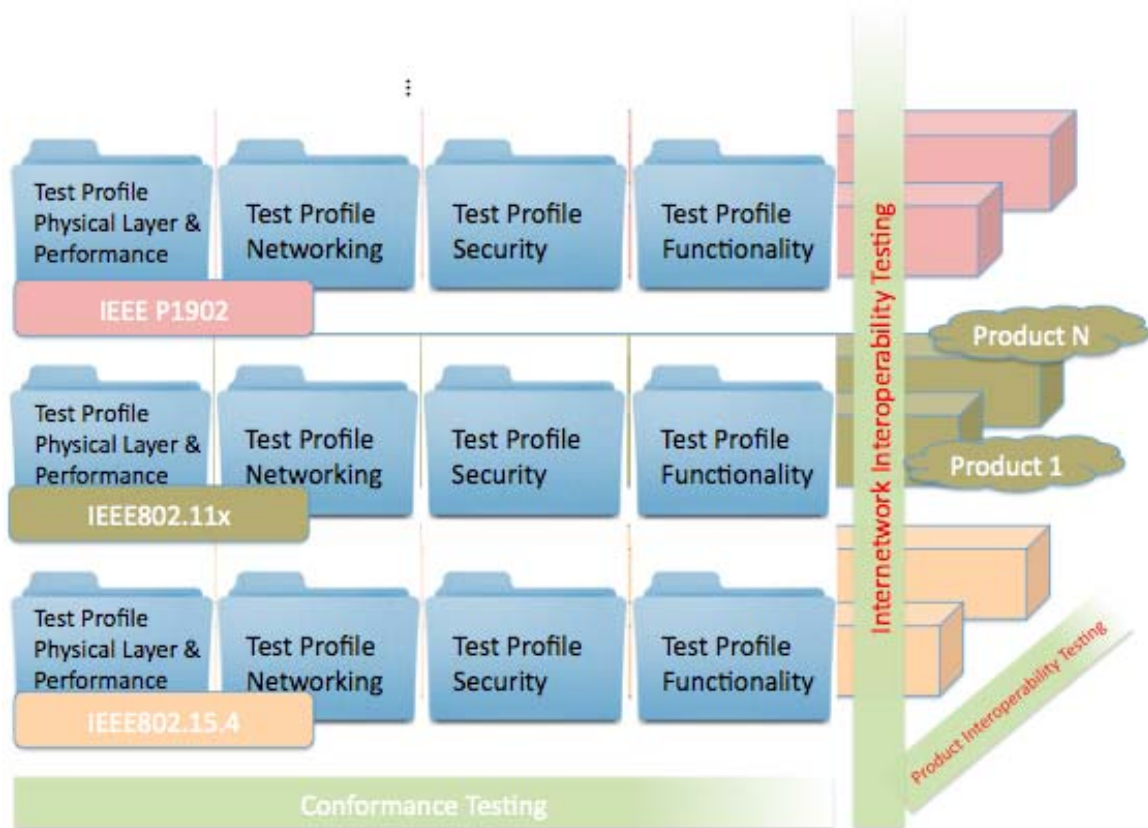

202

203

Interoperability Process Reference Manual (IPRM)

204 rate from interoperability testing. Nevertheless, conformance and interoperability testing
205 are interrelated in a matrix relationship.
206

207
208 **Figure 4 – Product Conformance And Interoperability Testing Matrix**

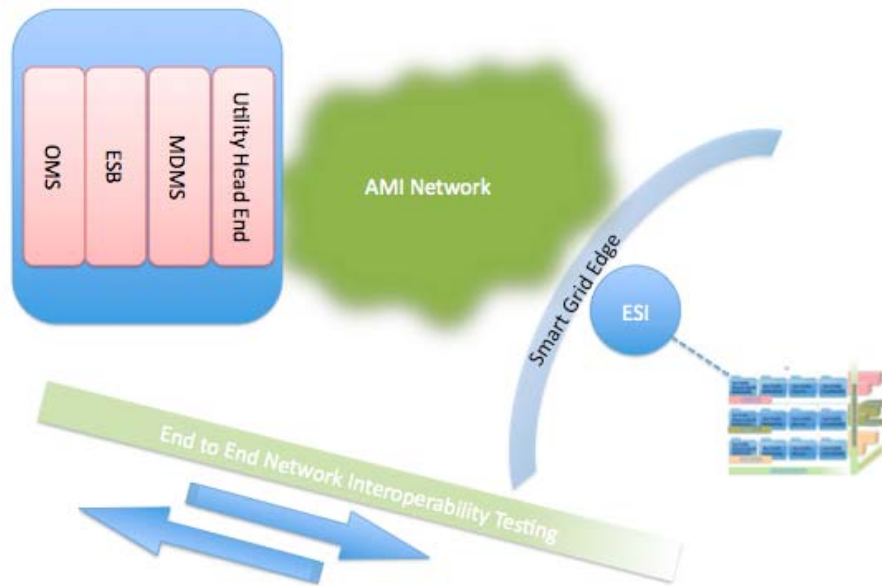

209
210 As shown in Figure 4, the Y-axis represents internetwork interoperability (i.e. transactions
211 between different physical layer implementations via routing systems) while the Z-axis
212 represents inter-product interoperability related to interaction between different instances of
213 a particular set of physical networks.

214

Interoperability Process Reference Manual (IPRM)

215 Finally, the end-to-end network interoperability testing example in Figure 5 illustrates the
216 requirements of a smart grid utility when implementing a communications standard from the
217 meter head-end system to the edge realm.
218

219
220 **Figure 5 – End-to-End Network Interoperability Testing**

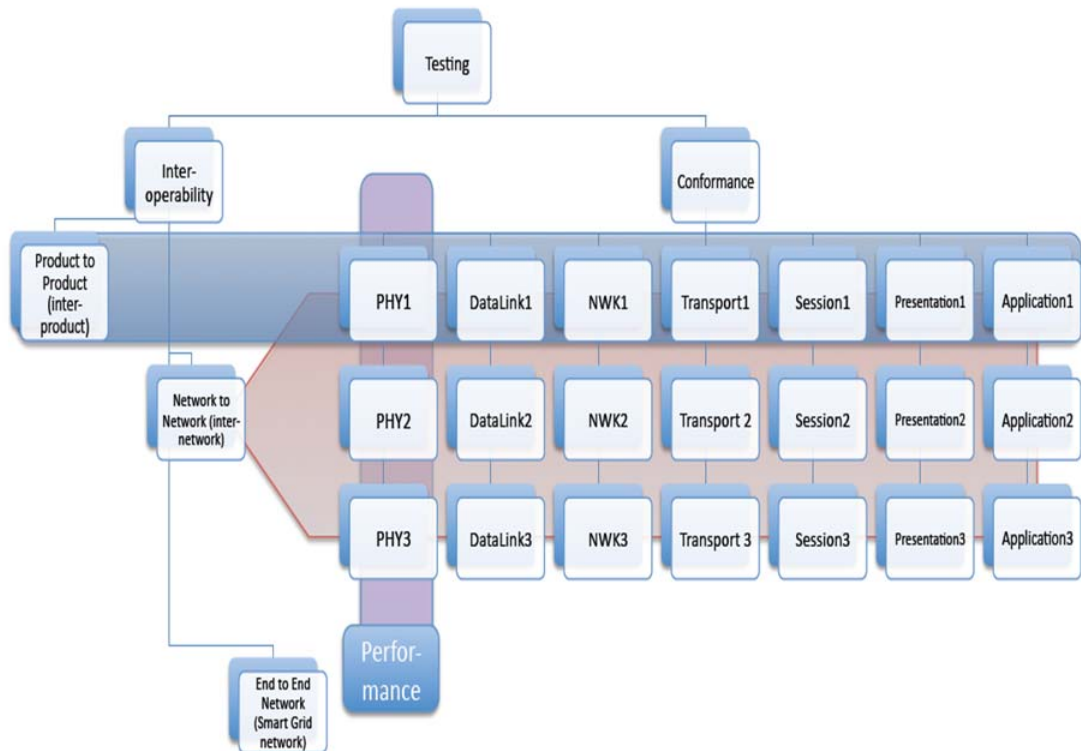

221
222 In summary, interoperability testing is not only relevant for product-to-product interoperabil-
223 ity but also for inter-network and end-to-end network interoperability.

224
225 Figure 6 shows the relationship between conformance and interoperability testing.

226

Interoperability Process Reference Manual (IPRM)

227

228

Figure 6 – Conformance and Interoperability Testing Relationship

229

230

A full coverage of all use cases and resultant test cases, and verification against all instances of products is the only way to ensure full deterministic interoperability. Generally, practical considerations make a full coverage impractical. Hence this document assumes statistical coverage of use cases and test cases, and therefore by default, the product interoperability discussed here is generally statistical in nature.

235

236

5.2 Scope of ITCA Categories

237

Communications technologies have typically followed certain methods to verify interoperability, and these methods are reviewed in this section based on their category. Each ITCA

238

Interoperability Process Reference Manual (IPRM)

239 category addresses different scopes of communication, networking, or business layers and
240 logic.

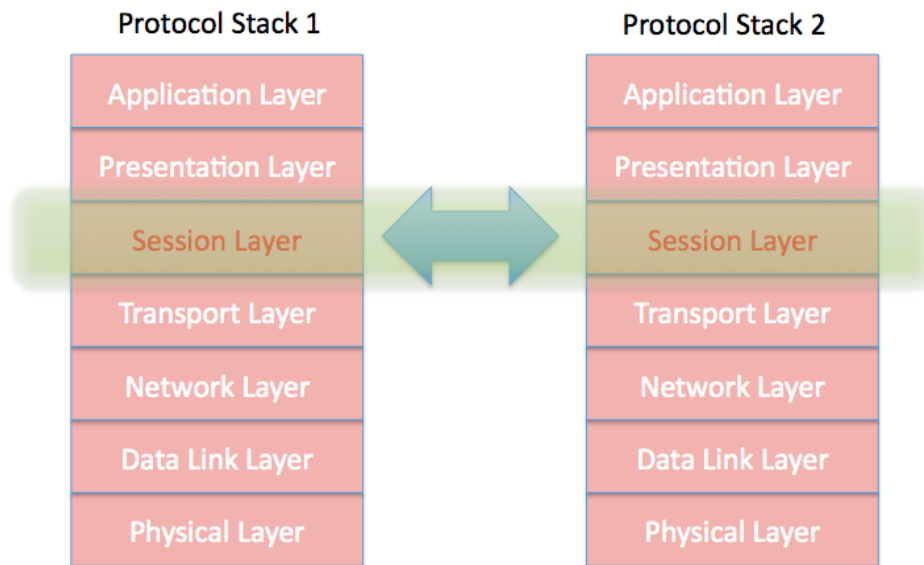

241

242 5.2.1 Category I ITCA:

243 Manages testing and certification programs for communication technologies involv-
244 ing one or more layers from layers 3-7 of the OSI stack. Typically it involves verifi-
245 ing the application level pair-wise communication between two product implemen-
246 tations of a standard.

247

Example: Category 1

e.g. SSL/TLS session established by a public key interchange

248

249

Figure 7 – Example of Category I ITCA

250

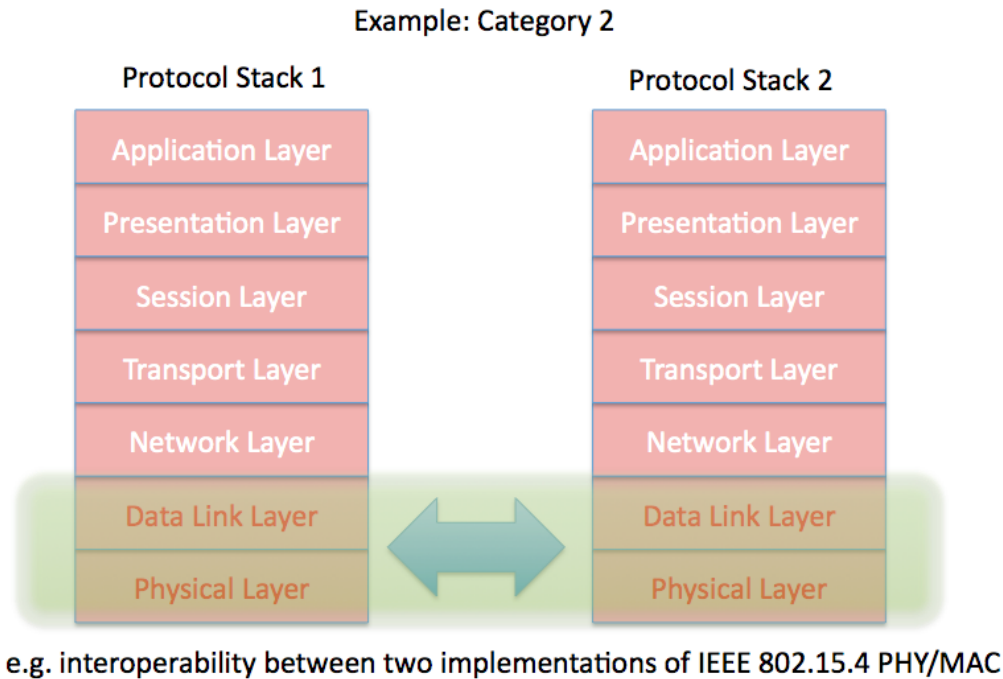

5.2.2 Category II ITCA:

251 The Category II ITCA manages testing and certification programs for platform² level
252 communication protocols. This includes Physical and Data Link Layer confor-
253 mance testing, interoperability testing, and performance testing.

Interoperability Process Reference Manual (IPRM)

254

255

256

Figure 8 – Example of Category II ITCA

257

5.2.3 Category III ITCA:

258

259

260

261

262

263

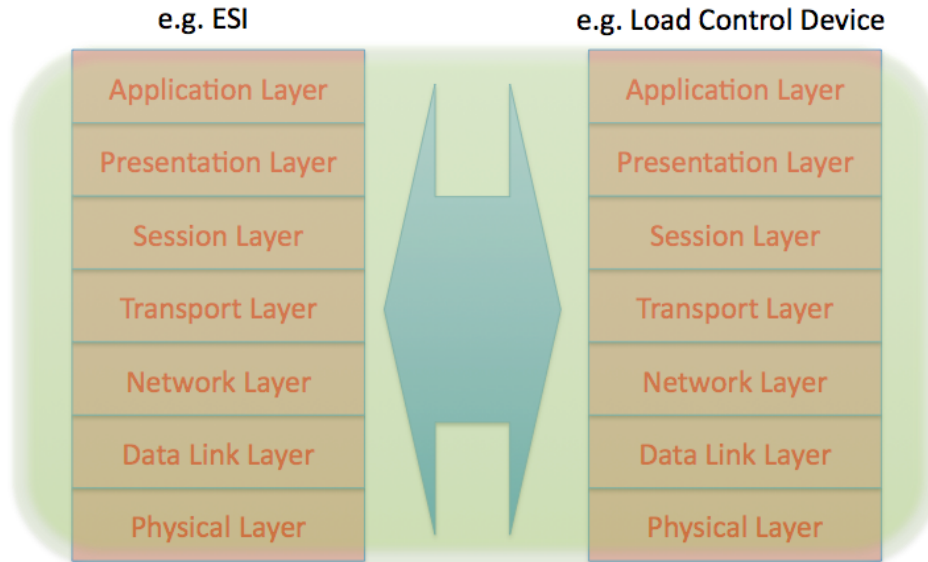

264

The Category III ITCA manages testing and certification programs for communication technologies corresponding to Physical and Data Link Layer and one or more of the higher layers. The Category III ITCA includes Category II ITCA, protocol conformance testing above PHY / MAC layers and device level or product level interoperability testing. The Category III ITCA may also rely on Category II ITCA certificates when sufficient inheritance rules are defined and agreed upon.

Interoperability Process Reference Manual (IPRM)

Example: Category 3

e.g. interoperability between products

Figure 9 – Example of Category III ITCA

265

266

267

268

5.2.4 Category IV ITCA:

269

270

271

272

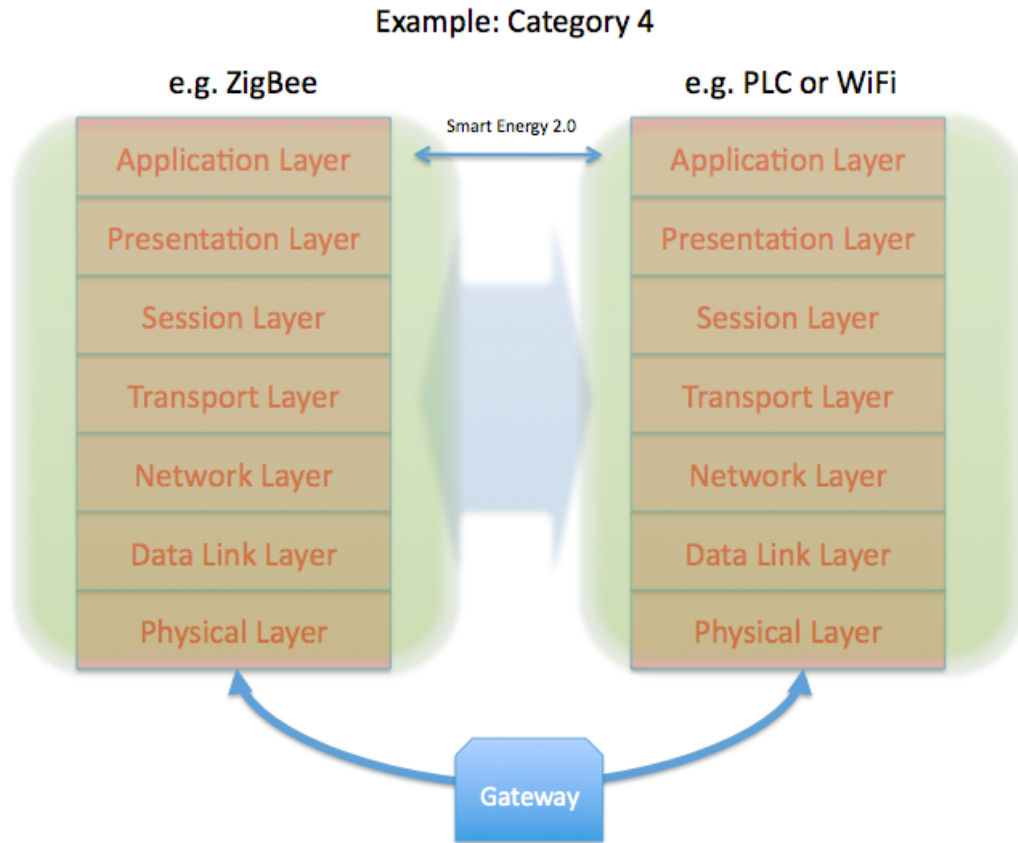

273

274

The Category IV ITCA manages testing and certification programs for communication technologies based on standards requiring interoperability between dissimilar physical networks. The Category IV ITCA includes Category II ITCA and Category III ITCA certification results, as well as the certification of interoperability for other relevant layers.

Interoperability Process Reference Manual (IPRM)

e.g. interoperability between networks

275

276

Figure 10 – Example of Category IV ITCA

277

5.2.5 Category V ITCA:

278

279

280

281

282

The Category IV ITCA manages testing and certification programs for communication inter-networking technologies, and incorporates Category I, II, III or IV ITCA testing results depending on the standard and system level interoperability required by a deployment. End-to-End network interoperability testing (e.g. simulating a back office network) is typically involved as part of the Category V ITCA.

283

284

Any category standard can require a Category V ITCA if the standard also specifies behavior associated with communicating with a third party (e.g., utility back office

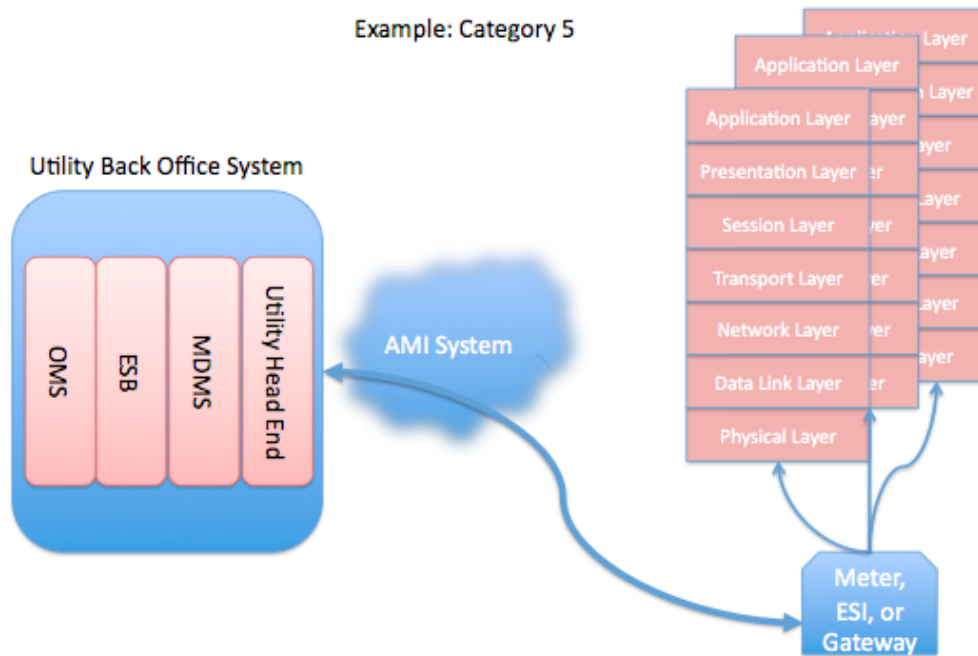

Interoperability Process Reference Manual (IPRM)

285 system). In this case, the Category V ITCA shall specify test cases that capture the
286 desired behavior (e.g. simulate a utility back-office system).

287
288 Other than the above requirement, a Category V ITCA shall follow the requirements
289 stated elsewhere in this document depending on the type of standard it specifies
290 (i.e. Category I, II, III, or IV ITCA). Smart Energy Profile 2.0 is an example of a
291 Category V ITCA standard since the standard describes registration to a service
292 provider network.

293
294

e.g. end to end interoperability

295
296
297

Figure 11 – Example of Category V ITCA

Interoperability Process Reference Manual (IPRM)

298 **5.2.6 Business Reference Authority:**

299 Depending on the standard, there might be a need for an additional layer of author-
300 ity testing to enforce additional specific requirements for a standards-based tech-
301 nology. This document recognizes the importance of such entities, but does not
302 specify requirements for such entities since their scope varies greatly based on the
303 business requirements.

304 As an example, the development and integration of the Smart Meter Texas portal to
305 support energy management programs using Smart Energy Profile 1.0 was based
306 on business processes defined within the State of Texas. The business processes
307 further defines the operational aspects of the integrated solution which ultimately
308 affects the product interoperability test cases.

Interoperability Process Reference Manual (IPRM)

309 6.0 Product Testing

310

311 6.1 Testing Scope and Administration

312 Testing for conformance and interoperability requires considerations for the overall test
313 coverage as illustrated in Figure 12. A test suite generally represents a set of test cases in
314 each of the categories (e.g., network test suite) represented in the diagram. A test profile
315 can be defined for an element of that category, along with various test suites and test re-
316 sources² such as test harnesses. A test campaign can represent a test profile implementa-
317 tion or specific test suites; in either case, the campaign defines the scope of testing and
318 the administration related to management of the process.

319

320 ITCA is expected to dependably manage a testing program. The details of the actual
321 process control are described as part of the Testing Program outlined in section 6.2.

322

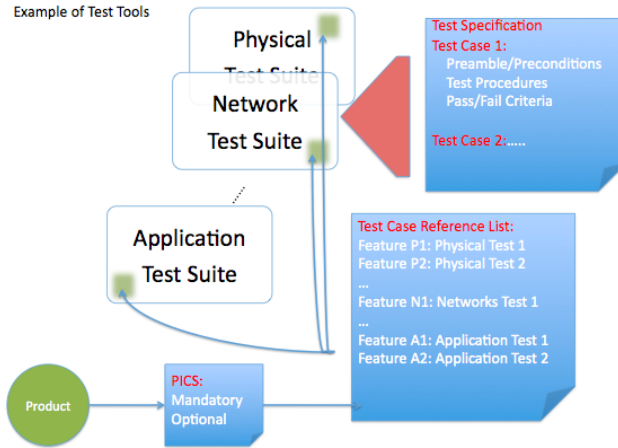

323 For each test suite, basic administrative controls are required and formalized using testing
324 resources such as PICS, test case reference lists, version control, test laboratories, and
325 validated test harnesses. The record of administrative control is outlined in the test plan,
326 test report and product compliance folder². It should be noted that a test harness² and test
327 interfaces² shall follow the architecture according to ITU X.291.

328

² See Glossary of Terms.

Interoperability Process Reference Manual (IPRM)

329

330

Figure 12 – Product Test Planning

331

332

333

334

Figure 12 also illustrates a process in which the product, with its mandatory and optional features per declared PICS, is processed for test planning using the Test Case Reference List and a subsequent test implemented according to the test specifications.

Interoperability Process Reference Manual (IPRM)

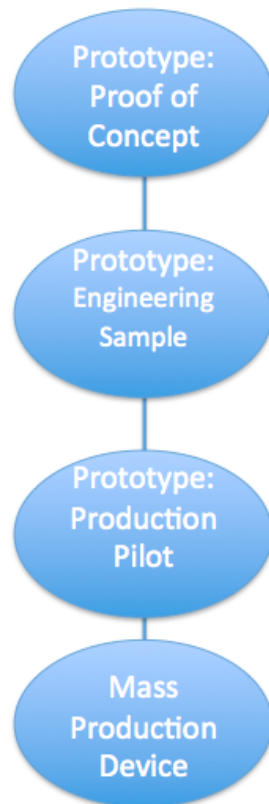

335 7.0 Testing Program

336 7.1 Testing Process Management

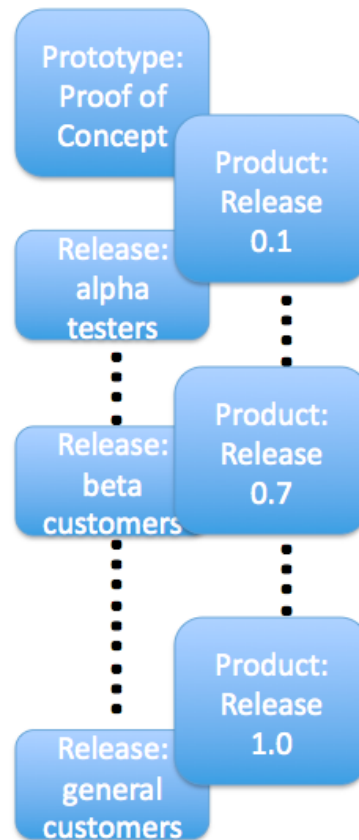

337 Testing processes are often developed separately from the product development process.
338 This provides for a level of technical independence that makes good testing rigorous and
339 objective. At the same time, it creates a conflict with certain realities of product develop-
340 ment, both in the hardware and software realm. Figure 13 depicts a typical product life cy-
341 cle process which is used in delivering a product to market. Previous sections in this
342 document provide a context in which these processes are applied in a particular test cam-
343 paign.

344

Product Life Cycle- Device

Product Life Cycle- Software (Agile)

345

357
358
359
360
361
362
363

Product certification through testing ostensibly needs to happen at the end of the process depicted in the diagram. With respect to hardware, product certification lies somewhere between the production pilot and mass production processes. As for software, product certification is performed before the general release of the software (i.e. version 1.0) to customers. However, economic reality dictates that changes resulting from test evidence should happen as early in the process as possible. This requires that during each and every step of the product development process, it is in the best interest of both the manufacturers and the ITCA to provide frequent certification program-related testing resources² throughout the process. Frequent testing reduces the total cost of the product and increases market acceptance, since problems are detected early and folded into the design of the product.

To address the need for frequent testing, third-party test laboratories are used for pre-testing. ITCA-sponsored testing events are organized to facilitate the introduction of a fully conforming and interoperable product into the market

Interoperability Process Reference Manual (IPRM)

364
365 **Figure 14 – Transition From Pre-Testing / Engineering Testing To Certification Testing**
366

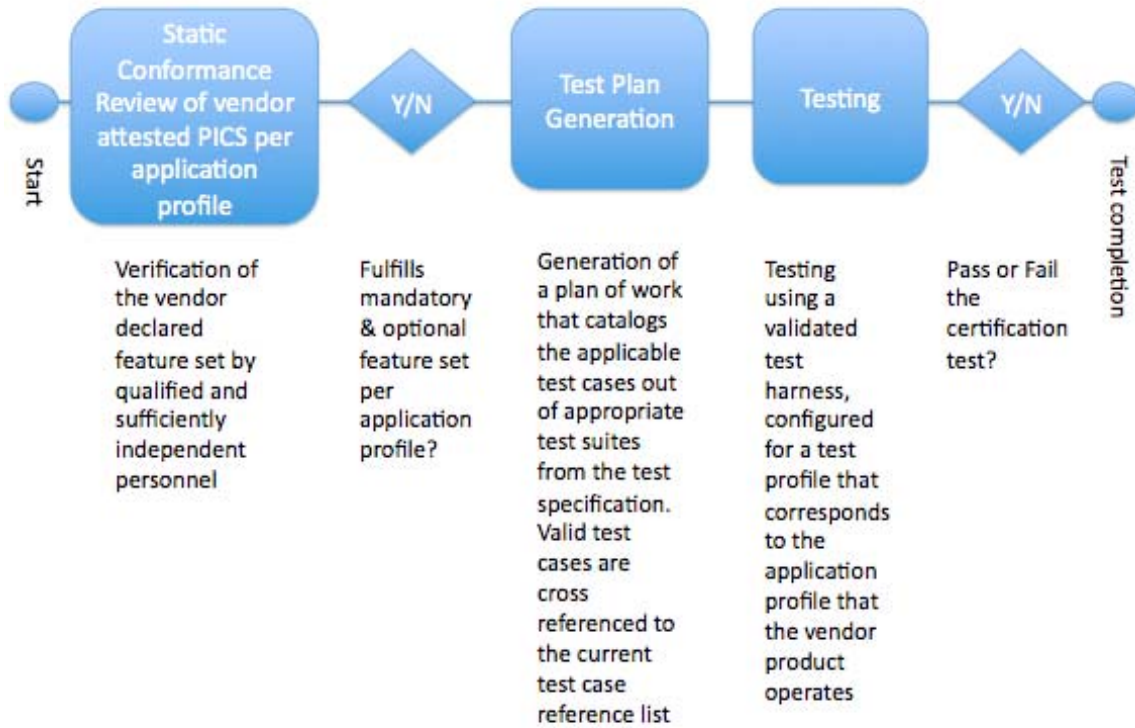

367 The transition from ITCA-sponsored pre-testing / engineering testing to certification testing,
368 as noted in Figure 14, may not always be as clear-cut when the service is rendered by an
369 ITCA-validated third-party test laboratory. Rigor is injected into the process by third-party
370 laboratories by their having a test service management system adhering to ISO Guide
371 17025..

372 **7.2 Certification Testing for Conformance and Interoperability**

373 Once testing moves to the Conformance and Interoperability Certification Testing phase
374 with the test laboratories, the following steps are generally expected. Note that this may
375 happen at any point in the product development process, and that when it is prior to the
376 end of the development cycle, it is the responsibility of the vendor together with the test
377 laboratory, per their test service management system, to fulfill the canonical steps de-
378 scribed in Figures 15 and 16 for certification related testing.

Interoperability Process Reference Manual (IPRM)

380

381

Figure 15 - Conformance and Interoperability Certification Testing – Part 1

382

Interoperability Process Reference Manual (IPRM)

Figure 16 – Conformance and Interoperability Certification Testing – Part 2

The process denoted in Figures 15 and 16 is implemented by a test laboratory for certification testing of conformance and interoperability. The roles and responsibility of individual experts may differ with each ITCA. One key point to recognize is the independence of the product vendor, tester, qualifier, and certifier processes.

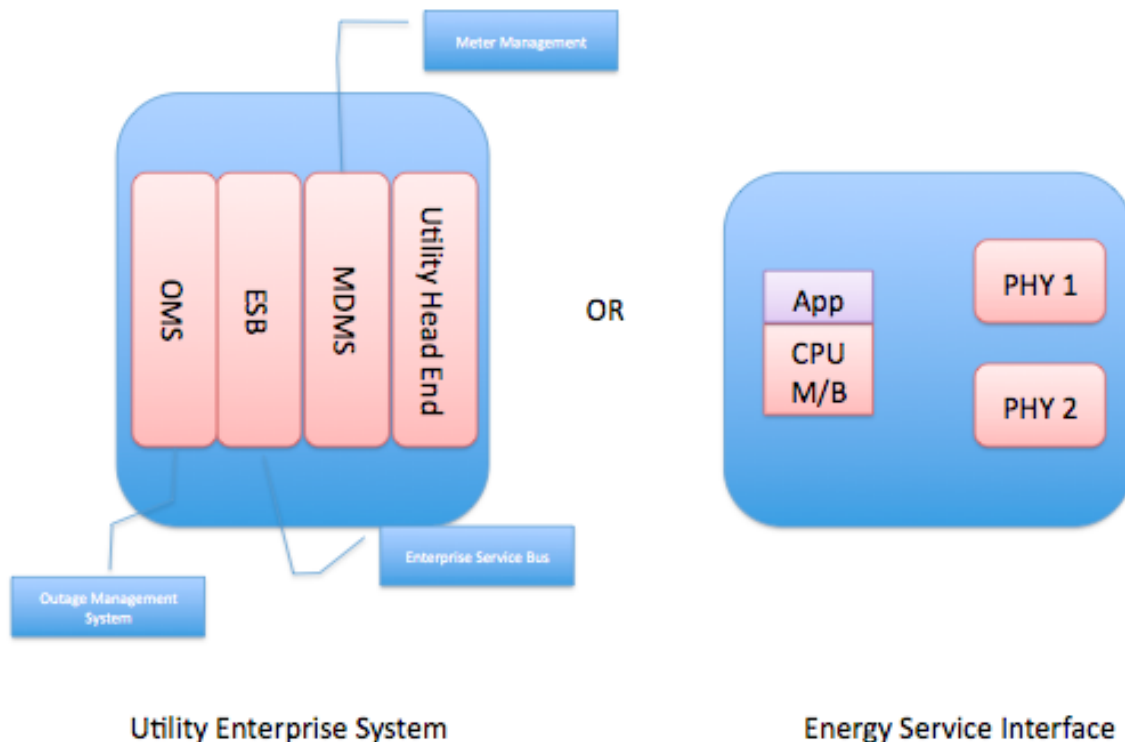

7.3 Products and Product Systems

The testing and certification process will be applied to products being implemented as smart grid technology. In certain instances, products are composed of components which are used to build a total product system. In such cases, components or "subsystems" may be subject to separate and inheritable certification processes by the ITCA.

Interoperability Process Reference Manual (IPRM)

Examples of System and Subsystem / Components

Utility Enterprise System

Energy Service Interface

396
397
398
399
400
401
402
403
404
405
406

Figure 17 – Examples of System and Subsystem / Components

In figure 17, a large enterprise utility software system and an edge in-premise energy service interface device are given as examples of a system and subsystem / components. Any one of the components of the respective integrated product may be subjected to testing under the ITCA requirements, and its results may or may not be inheritable by the integrated system. The successful inheritance by an integrated system depends on the test coverage and the version of the testing applied to the subsystem, and the version of the subsystem itself.

Interoperability Process Reference Manual (IPRM)

407 The record of work of the subsystem component, or the system test, is stored in the com-
408 pliance folder of the product. The compliance folder will include the detail of the Compliant
409 Portion Description (CPD)³ of the subsystem, if it is to be inheriting the certified test status
410 of that subsystem and integrating it into the whole system. In such a case, the system cer-
411 tification is additive of the CPDs of constituent components, but may still need additional
412 tests based on test coverage as defined by relevant applicable test for the application pro-
413 file for the product in question, and as defined by the test plan derived from the PICS, Test
414 Case Reference List, and Test Specification.

³ See Glossary of Terms for definition and explanation of CPD

Interoperability Process Reference Manual (IPRM)

415 **8.0 Interoperability Testing And Certification Authority Role And** 416 **Requirements**

417 The ITCA shall provide governance and coordination for the maintenance and administration of
418 Interoperability Testing Laboratories and Certification Bodies in cooperation with the relevant SSOs
419 and user groups. An ITCA shall manage the end-to-end processes associated with interoperability
420 testing and certification. It is assumed that the ITCA has the appropriate infrastructure in place to
421 support this function. Although beyond the scope of the IPRM, if a new ITCA is being launched,
422 establishment of the following is recommended:

- 423 • Business plan
- 424 • Clear governance structure and IPR policy
- 425 • Testing lab(s)
- 426 • Certification body / bodies
- 427 • Security certificate authority
- 428 • Technical Lead(s)

429 The following information shall be used as a guide by the ITCA to improve the interoperability and
430 quality of a Smart Grid standards based product.

431 **8.1 Interoperability Requirements For Use By The ITCA**

432 The interoperability requirements are comprised of five major categories which will be used
433 by the ITCA to effectively manage the testing and certification organization processes. The
434 five major categories are:

- 435 • Governance
- 436 • Lab Qualification
- 437 • Technical Design
- 438 • Improvement
- 439 • Security

440

Interoperability Process Reference Manual (IPRM)

441 The IPRM requirements are written with the key word “shall”. However, depending on the
 442 standard under consideration, only a subset of those requirements are relevant. The fol-
 443 lowing conventions are being used for classification:

- 444 • Basic (B) – Minimum requirement. The requirements shall be considered manda-
 445 tory and included to ensure interoperability.
- 446 • Optional (O) – Requirement identified as a use case for the business application,
 447 but shall not be considered mandatory as part of the interoperability testing.
- 448 • Not Applicable (N/A) – Requirement identified as a use case for the business ap-
 449 plication, but does not apply to the specified standard under consideration.

450 As mentioned in section 5.2.5 above Category V ITCAs are required to adhere to the re-
 451 quirements of Category I, II, III and IV ITCAs depending on the standard under considera-
 452 tion. However, in addition they shall satisfy requirements Tech 36 and Tech 37 below.

453

454 8.2 Governance

455 Governance defines the structures, policies, rules and regulations associated with the
 456 ITCA certification program. A governance process example would require the ITCA to es-
 457 tablish and maintain an independent and vendor neutral testing and certification oversight
 458 authority. The following list of Interoperability Governance Process Requirements provided
 459 in Table 1 shall be considered governance process requirements for managing the interoper-
 460 ability testing and certification programs.

461

462

| Govern-x | Interoperability Governance Process | ITCA Category | | | |
|----------|---|---------------|----|-----|----|
| | Requirement Description | I | II | III | IV |
| Gov-1 | An interoperable standard shall have an entity identified as the ITCA. This entity shall be responsible for | B | B | B | B |

Interoperability Process Reference Manual (IPRM)

| | | | | | |
|-------|--|---|-------|---|---|
| | ensuring that implementations are in fact interoperable. ⁴ | | | | |
| Gov-2 | An ITCA shall be considered valid as long as its users' community considers it valid, and when there exists three or more distinct implementations of the specification for which the three distinct implementations are from three different entities. These three or more distinct implementations must be available or declared available. Note: If the three distinct entities declare intent to implement the specification, this requirement is satisfied. | B | B | B | B |
| Gov-3 | The ITCA certifying the highest layer of technology under test shall not declare an implementation as interoperable if it discovers interoperability problems at a lower layer (e.g. the ITCA responsible for application layer testing returns the product to lower layer ITCAs for further investigation of non-interoperable features). | B | N / A | B | B |
| Gov-4 | The ITCA shall clearly define the circumstances in which it supports first party testing. | B | B | B | B |
| Gov-5 | The ITCA shall clearly identify the circumstances in which third-party testing is required. | B | B | B | B |
| Gov-6 | The ITCA shall define a corrective process for resolving interoperability problems (e.g. in the field or as part of the test). ⁵ Further, it shall implement preven- | B | B | B | B |

⁴ Situations where a clear ITCA does not exist are out of scope of this document. The SGTCC will tackle issues where clear ITCAs do not exist in a separate effort.

⁵ The ITCA should use best efforts in contacting a standards body with respect to a specification; however, it not their responsibility to resolve issues with the specification.

Interoperability Process Reference Manual (IPRM)

| | | | | | |
|--------|---|---|---|---|---|
| | tative processes to avoid recurrence of such problems. A problem may be associated with the specification, the test processes and procedures or the test data. | | | | |
| Gov-7 | The ITCA shall define roles, responsibilities, and resource elements of the interoperability program in a concise document. | B | B | B | B |
| Gov-8 | The ITCA shall support a mechanism to raise issues up to steering bodies and liaison organizations for business, regulatory and standards interoperability considerations. | B | B | B | B |
| Gov-9 | The ITCA shall maintain a certified product and systems list. This list shall be publicly available. | B | B | B | B |
| Gov-10 | The ITCA shall maintain a test case reference and modification history list. ⁶ | B | B | B | B |
| Gov-11 | Test Suite Specifications (TSS) ⁷ used for interoperability or conformance testing shall be managed in a well-defined, open and formal manner with change control. | B | B | B | B |
| Gov-12 | A common TSS shall be established when multiple test labs are deployed to test the same standard and / or profile. If common unique test procedures are required to support this test suite, then they shall also | B | B | B | B |

⁶ See Glossary of Terms for definition and explanation of the test case reference list.

⁷ See Glossary of Terms for definition and explanation of the TSS.

Interoperability Process Reference Manual (IPRM)

| | | | | | |
|--------|--|---|---|---|---|
| | be defined. The TSS should be test tool agnostic. | | | | |
| Gov-13 | All certification bodies and ITCAs acting as certification bodies shall adhere to ISO / IEC Guide 65 principles, and requires auditing by outside third-parties. ⁸ | B | B | B | B |
| Gov-14 | The ITCA shall minimize divergence of interoperability requirements interpretations. ⁹ | B | B | B | B |
| Gov-15 | If an ITCA has multiple testing laboratories and certifying bodies, processes shall be in place to avoid quality differences and assure repeatable testing between the laboratories. | B | B | B | B |
| Gov-16 | The ITCA shall periodically re-examine their internal processes, best practices and tools based on corresponding specifications, and obtain a qualified third-party review per ISO guide 65. | B | B | B | B |
| Gov-17 | The ITCA shall ensure that the test labs and certification bodies maintain their accreditation for the specific standard under consideration. If a standard is not yet available for listing by an accreditation body, it shall be assured that the test facility overall maintains an accreditation and is being reviewed by the ITCA as technically able to test the standard. | B | B | B | B |

⁸ Some interpretations of ISO Guide 65 consider certification body membership requirements as non-conforming to the intent of ISO Guide 65 Section 4.1. The SGTC recognizes that many of the certification authorities supporting Smart Grid standards are member based organizations providing useful services. It is the view of the SGTC that membership based programs are acceptable in meeting the intent of its criteria and recommendations. As long as membership requirements are offered to any interested participants in a fair and unbiased process, meeting the other non-discriminatory criteria of ISO 65, this form of certification authority is acceptable to the SGTC.

⁹ One way to minimize divergence of interpretations is to limit the number of labs to only one. Another option for minimizing divergence are to have a technical lead (also known as a lead lab) responsible for properly interpreting conformance and interoperability issues.

469

Table 1 – Interoperability Process Governance Requirements

8.3 Lab Qualification

Lab qualification defines the requirements in Table 2 that shall be applied by ITCAs when recognizing testing laboratories. It should be noted that additional requirements are further detailed in ISO 17025.

| Lab-x | Interoperability Lab Qualification Process Requirement Description | ITCA Category | | | |
|-------|--|---------------|----|-----|----|
| | | I | II | III | IV |
| Lab-1 | In selecting test organizations, the ITCA shall have uniform and transparent procedures for evaluating test labs. | B | B | B | B |
| Lab-2 | The ITCA shall define requirements to qualify the personnel involved in the certification and testing processes per ISO 17025. | B | B | B | B |
| Lab-3 | The ITCA shall require that its test labs adhere to ISO 17025. | B | B | B | B |
| Lab-4 | Where applicable, the ITCA shall use existing laboratory qualification standards and schemes for evaluating test labs. | B | B | B | B |

475
476

Table 2 – Interoperability Lab Qualification Process Requirements

8.4 Technical Design for Interoperability and Conformance Program Design

The Technical Design for Interoperability and Conformance Program Design defines the requirements needed to effectively manage the procedures and processes associated with interoperability and conformance testing.

Interoperability Process Reference Manual (IPRM)

477

478

| Tech-x | Interoperability Technical Design Process | | ITCA Category | | | |
|--------|---|---|---------------|----|-----|----|
| | Category | Requirements Description | I | II | III | IV |
| Tech-1 | Technical | The ITCA shall specify in the test program requirements features that are mandatory, and those features that are optional. | B | B | B | B |
| Tech-2 | Technical | The ITCA shall require and enforce that vendors declare the optional features implemented in a product. | B | B | B | B |
| Tech-3 | Technical | If more than one vendor implements the same optional feature in a product, the ITCA shall require that future implementations of that optional feature be tested and certified for conformance and interoperability. Furthermore, the ITCA shall define common test cases for that optional feature to be used by all test labs when testing for that optional feature. | B | B | B | B |
| Tech-4 | Technical | Where market clarity is required, separate certificates ¹⁰ shall be associated with products implementing optional requirements. | B | B | B | B |
| Tech-5 | Technical | An ITCA shall have procedures and processes in place to retain a record of work | B | B | B | B |

¹⁰ See Glossary of Terms for definition of certificate.

Interoperability Process Reference Manual (IPRM)

| | | | | | | |
|--------|-------------|--|---|---|---|---|
| | | of the testing and certification process to be called a Compliance Folder or record of work. For example, a compliance folder per certified product could include test reports, revision control documents, description of the implementation, etc. | | | | |
| Tech-6 | Inheritance | The ITCA shall allow for sub-component (e.g., previously certified hardware modules used in developing final products, previously certified software components with well defined interfaces and dependencies etc.) inheritance in development of final products. However, it is the ITCAs responsibility to ensure that interoperability is maintained. | B | B | B | B |
| Tech-7 | Inheritance | The ITCA shall maintain a controlled list of compatible sub-components that can be inherited to build final products. This might include specifying compatible feature-sets. | B | B | B | B |
| Tech-8 | Inheritance | When supporting products composed of sub-components, the ITCA shall define the set of additional tests necessary to ensure interoperability (e.g. integration testing, final performance testing, etc.) | B | B | B | B |

Interoperability Process Reference Manual (IPRM)

| | | | | | | |
|---------|-------------------|--|---|---|---|---|
| Tech-9 | Inheritance | The ITCA shall implement a Compliant Portion Description (CPD) ¹¹ to be used as a guide for assembling a product based on compatible sub-components. | B | B | B | B |
| Tech-10 | Version Control | The ITCA shall have an explicit process in place to assess necessity of re-certification against subsequent release versions of a specification, including security. | B | B | B | B |
| Tech-11 | Version Control | The ITCA shall define the level of re-certification required for subsequent release versions of a specification. | B | B | B | B |
| Tech-14 | Version Control | The ITCA shall define a mechanism to identify the latest version of a previously certified product or system implementation. This is important in cases where a previously certified product or system has been upgraded to a different version. | B | B | B | B |
| Tech-15 | Version Control | The ITCA shall have a mechanism to enforce version control rules to ensure compliance (e.g. standards usually have to go back to the accreditation body if they are changing the version). | B | B | B | B |
| Tech-16 | Testing - General | The testing and certification program shall have common well-defined standardized test cases. These test cases | B | B | B | B |

¹¹ See Glossary of Terms for definition and further explanation of CPD

Interoperability Process Reference Manual (IPRM)

| | | | | | | |
|---------|-------------------|--|---|---|---|---|
| | | should be defined in an open, consensus-driven fashion, following ANSI-type processes. These test cases will be used by all test labs approved by the ITCA. | | | | |
| Tech-17 | Testing – General | There shall be a defined correlation between implementations and required testing, commonly called a Proforma Implementation Conformance Statement (PICS). ¹² | B | B | B | B |
| Tech-18 | Testing - General | The testing and certification program shall maintain a current and upcoming list of applicable test cases to be called a Test Case Reference List. | B | B | B | B |
| Tech-19 | Testing – General | There shall be a Test Plan derived from the Test Case Reference List and used by all authorized test labs. Tests shall be identified using the test plan. | B | B | B | B |
| Tech-20 | Testing – General | The testing and certification program shall require that a static conformance review ¹³ take place prior to testing a product. | B | B | B | B |
| Tech-21 | Testing – General | The testing and certification program shall first validate the tests, and implement them utilizing validated test tools. Golden reference test equipment may be | B | B | B | B |

¹² PICS can be referred as both Protocol Implementation Conformance Statement and Profile Implementation Conformance Statement. Proforma is being used in this requirement to reference both concepts.

¹³ See Glossary of Terms for the definition and explanation of a static conformance review.

Interoperability Process Reference Manual (IPRM)

| | | | | | | |
|---------|--------------------------|---|---|---|---|---|
| | | utilized where appropriate. | | | | |
| Tech-22 | Testing – General | The TSS shall be subject to revision control, including revision history, revision numbering, and a defect and expansion management process. The TSS should clearly identify the test purpose, references, resource requirements, test setup, procedures, observable results and possible problems / lessons learned with the test approach. Observables should clearly identify pass / fail / indeterminate requirements and informational elements. | B | B | B | B |
| Tech-23 | Testing - Conformance | The testing and certification program shall assure that defined product test cases cover application profiles for specific feature sets and functions defined by the specific application profile, and implement interoperability evaluation within that application profile. | B | B | B | B |
| Tech-24 | Testing – Conformance | Where practicable, the testing and certification program shall assure that defined product test cases cover all feature sets and functions. | B | B | B | B |
| Tech-25 | Testing – Conformance | The testing and certification program shall define and evaluate based on concise pass / fail criteria, yet allowing for inconclusive outcomes. Note: An in- | B | B | B | B |

Interoperability Process Reference Manual (IPRM)

| | | | | | | |
|---------|------------------------------------|---|-----------------|-------|---|-----------------|
| | | conclusive test run cannot result in certified products. Inconclusive test results shall be investigated to clearly identify what is required to move out of the inconclusive state. | | | | |
| Tech-26 | Testing – Conformance | The testing and certification program shall define conformance testing per OSI 7-layer, and end-to-end testing from the physical to the application layer as relevant and necessary. | B | B | B | B |
| Tech-27 | Testing – Product Interoperability | The testing and certification program shall assure that defined product use cases are covered in application profiles. Interoperability testing and evaluation shall be implemented within those application profiles. | B ¹⁴ | N / A | B | B ¹⁵ |
| Tech-28 | Testing – Product Interoperability | The testing and certification program shall classify common or major market products according to their application profiles, and include them as part of an interoperability evaluation for those specific profiles. The evaluation shall make use of test profiles correlated to those specific applications. ¹⁶ | B ¹⁷ | B | B | B ¹⁷ |

¹⁴ Only basic for category I ITCAs that tackle the application layer.

¹⁵ Can be N/A for category IV ITCAs that correlate to Category II standards.

¹⁶ Interoperability testing is tied to market realities. Hence the testing and certification program needs to have a mechanism to adopt representative market products as an integral part of interoperability testing.

¹⁷ Only a basic requirement for those ITCAs that correlated with application layer standards.

Interoperability Process Reference Manual (IPRM)

| | | | | | | |
|---------|------------------------------------|---|---|---|---|-----------------|
| Tech-29 | Testing – Product Interoperability | The testing and certification program shall ensure that venues are provided for multi-vendor and multi-product communication and interchange evaluations (i.e. “plug fests”). This program may be optional for ITCAs correlated to standards resulting in application interfaces and not a physical product (e.g. OpenADE). ¹⁸ | O | B | B | B ¹⁸ |
| Tech-30 | | Prototyping of draft standards or major revisions shall be supported via multi-vendor / multi-product testing. The ITCA shall solicit for the prototyping of draft standards or major revisions, and organize multi-vendor / multi-product testing. It is recommended that the prototyping take place in the late stages of standards development in order to verify the correctness of the standard, verify the test suites and verify that the anticipated interoperability or conformance testing is debugged. | O | B | B | B ¹⁸ |
| Tech-31 | Testing – Product Interoperability | The ITCA shall have a process to select a minimum of two distinct reference implementations as golden implementations or golden units. The selection is usually based on the results of the interoperability testing. All other implementations | O | B | B | B ¹⁸ |

¹⁸ Can be optional for Category IV ITCAs that correlate to Category I standards.

Interoperability Process Reference Manual (IPRM)

| | | | | | | |
|---------|------------------------------------|--|---|---|---|-----------------|
| | | shall be tested against these golden implementations. ¹⁹ | | | | |
| Tech-32 | Testing – Product Interoperability | The ITCA shall make appropriate provisions for the use of golden implementations in the testing and certification program to strengthen consistent and standard implementation and interoperability testing and certification processes. | O | B | B | B ¹⁸ |
| Tech-33 | Testing – Product Interoperability | The golden implementations or golden units shall be clearly associated with each version of the standard. Each golden unit is a snap shot (instantiation) of each version of the standard. | O | B | B | B ¹⁸ |
| Tech-34 | Testing – Product Interoperability | The testing and certification program shall ensure that critical vendor implementations be made available to the labs as golden implementations. | O | B | B | B ¹⁸ |
| Tech-35 | Testing – Product Interoperability | The testing and certification program shall define interoperability testing per OSI – 7 layer or per collection of layers, and end-to-end testing from the physical to the application layer as relevant and necessary. | O | B | B | B ¹⁸ |
| Tech-36 | Testing – | If a Smart Grid standard impacts and / or | B | B | B | B |

¹⁹ The industry prefers three golden units for product testing, but the minimum number of golden units shall be no less than two golden units.

Interoperability Process Reference Manual (IPRM)

| | | | | | | |
|---------|-----------------------------------|--|---------------------------------|---------------------|---------------------|-----------------------------|
| | System Interoperability | crosses multiple Smart Grid systems, then the responsible ITCA ²⁰ shall ensure that venues are provided that support end-to-end testing of Smart Grid systems involving multiple vendors. | | | | |
| Tech-37 | Testing – System Interoperability | A category V ITCA shall involve all relevant parties to define various business logic models for the end-to-end system testing, and make scenarios and test harness systems available for testing. | N / A ² ₁ | N / A ²¹ | N / A ²¹ | N / A ²¹ |
| Tech-38 | Testing - Performance | The testing and certification program shall ensure that when functional performance requirements are defined in an application profile, the performance test profile(s) shall be designed to implement test cases for evaluating these requirements. | B ¹ ₇ | N / A | B ¹⁷ | B ¹ ₇ |
| Tech-39 | Testing – Performance | The testing and certification program shall define test performance per OSI – 7 layer, and end-to-end testing from the physical to the application layers as relevant and necessary. ²² | B | B | B | B |
| Tech-40 | Tools | The ITCA shall validate test cases, intro- | B | B | B | B |

²⁰ This is a category V ITCA as described in section 5.2.5. This can remain a Basic requirement for all ITCAs since it is a conditional statement.

²¹ This is only N/A for Category I, II, III, IV ITCAs who are not also category V ITCAs.

²² This is a different requirement than requirement Tech-26 and Tech-35. Tech-26 specifies conformance testing, tech-35 specifies interoperability testing, and this requirement specifies performance testing requirements.

Interoperability Process Reference Manual (IPRM)

| | | | | | | |
|---------|----------------|--|---|---|---|---|
| | | duce standardized test tools and reference implementations as validated tool sets where appropriate. | | | | |
| Tech-41 | Tools | The ITCA shall ensure that test tools have a complete mandatory feature-set coverage of a standard. In cases where two or more implementations of optional features are available, the ITCA shall incorporate those feature-sets in the test tool. ²³ | B | B | B | B |
| Tech-42 | Tools | The ITCA shall define procedures and processes to validate the use of test tools and reference implementations. | B | B | B | B |
| Tech-43 | Technical Lead | The ITCAs shall identify an entity (e.g. lab, person, committee etc.) as the technical lead. This technical lead is the responsible authority for ITCAs technical conformance and interoperability matters. Note: The ITCA is the administrative organization, whereas the technical lead has the technical expertise to resolve technical testing and certification issues. | B | B | B | B |
| Tech-44 | Technical Lead | A technical lead(s) shall be responsible for verification of new test cases, valida- | B | B | B | B |

²³ Effective test tools need to be able to test all features and functions of a standard. Some features of a standard may never be supported by certain products; however when a standard is published, the industry is free to implement optional feature set in addition to the mandatory set; lack of testing capability of optional feature sets hinders interoperable feature set introduction. Normally, validated test tools have implementations of all features, including optional ones as a condition for the tool validation.

Interoperability Process Reference Manual (IPRM)

| | | | | | | |
|---------|----------------|--|---|---|---|---|
| | | tion of test tools, resolution of interoperability problems, and other issues of technical discrepancies where the testing laboratories and certification bodies require guidance. | | | | |
| Tech-45 | Technical Lead | A technical lead shall not commercially compete with testing laboratories and certification bodies | B | B | B | B |
| Tech-46 | Technical Lead | The ITCA and the technical lead shall remain neutral to testing laboratories and certification bodies. | B | B | B | B |

481
482
483
484

8.5 Improvements

The Improvements section outlines the controls that will need to be in place to support the interoperability testing processes.

| Improv-x | Interoperability Improvements Process Requirements Description | ITCA Category | | | |
|----------|---|---------------|----|-----|----|
| | | I | II | III | IV |
| Improv-1 | The ITCA shall implement monitoring and auditing programs to ensure adherence to its policies.. | B | B | B | B |
| Improv-2 | The ITCA shall establish a checklist for the auditing of the appointed evaluation laboratories. | B | B | B | B |
| Improv-3 | The ITCA shall periodically audit the laboratories at appropriate intervals to ensure laboratories uphold necessary capabilities. | B | B | B | B |

Interoperability Process Reference Manual (IPRM)

| | | | | | |
|----------|---|---|---|---|---|
| Improv-4 | The ITCA shall establish an auditing procedure and implement audits to verify that product interoperability is maintained after the product passes the testing and certification programs and enters the market. | B | B | B | B |
| Improv-5 | The ITCA shall have processes in place, including corrective and preventative actions, which results in continual improvement of their testing and certification programs. | B | B | B | B |
| Improv-6 | The ITCA shall be in constant communication with the standards writing committees to create a feedback loop. For example, the ITCA should define a process to communicate the TSS test results back to the SSOs and stakeholders. | B | B | B | B |
| Improv-7 | The ITCA shall provide a forum for feedback to be received from a stakeholder, interested business party and use case in order to improve its interoperability best practices. | B | B | B | B |
| Improv-8 | It is preferred that ITCAs have a method for actively soliciting interoperability feedback on implementations of the standard in order to achieve some level of customer and user-community satisfaction on that feedback. | B | B | B | B |

Table 4 – Interoperability Improvements Process Requirements

485

486

487

8.6 Cyber Security

Interoperability Process Reference Manual (IPRM)

488 The Cyber Security section outlines the requirements which shall be used by the ITCA to
 489 validate the security-related components of the interoperability testing program.
 490

| Sec-x | Cyber Security Improvements Process Requirements Description | ITCA Category | | | |
|-------|--|---------------|----|-----|-----------------|
| | | I | II | III | IV |
| Sec-1 | The ITCA shall define the procedures and processes which will be used to validate interoperability cyber security requirements. | B | B | B | B |
| Sec-2 | The testing and certification program shall ensure that cyber security functional performance requirements are defined, and test cases designed to evaluate the requirements. | B | B | B | B |
| Sec-3 | Where applicable, the ITCA shall have a process in place to select and implement a Digital Certificate Issuance mechanism that may include the election of a Certificate Authority. The energy service providers can use this certificate for authentication that a given product has actually been certified. ²⁴ | O | B | B | B ²⁴ |
| Sec-4 | The ITCA shall be responsible for certificate management including issuance, maintenance and policing. The ITCA can choose to outsource this responsibility as long as they remain responsible for the interoperable outcome. ²⁴ | O | B | B | B ²⁴ |
| Sec-5 | The ITCA shall implement a process to qualify testing personnel at an appropriate level for their cyber security test training and experience. | B | B | B | B |

²⁴ Optional for ITCAs that result in interfaces and not result a physical product.

Interoperability Process Reference Manual (IPRM)

| | | | | | |
|--------|--|---|---|---|---|
| Sec-6 | The ITCA shall specifically require a test methodology that includes widely-accepted stress testing processes including static analysis and penetration testing. | B | B | B | B |
| Sec-7 | The ITCA shall assure that cyber security models are policy driven, and testing shall also be based on policy settings. | B | B | B | B |
| Sec-8 | The ITCA shall ensure that processes are in place for vendors to submit threat analysis as part of the certification process. | B | B | B | B |
| Sec-9 | The ITCA shall leverage and align with existing security test programs. | B | B | B | B |
| Sec-10 | The ITCA shall ensure that processes are in place to incorporate component-based cyber security concepts in the testing program. | B | B | B | B |
| Sec-11 | The ITCA shall ensure that all business, system, and technical interests are represented in the testing program. | B | B | B | B |

Table 5 – Interoperability Cyber Security Process Requirements

491

492

Interoperability Process Reference Manual (IPRM)

493 9.0 Best Practices For Interoperability and Conformance Test 494 Construction

495 This section provides best practices and guidelines for ITCAs in their development and operation of
496 interoperability and conformance testing programs. The recommendations provided in this section
497 were generated based on input from experienced testing organizations that have evolved interoper-
498 ability and conformance programs through lessons-learned in executing tests for both software
499 and hardware applications.

500

501 This section addresses general testing policies, test suite specifications (TSS) and test profile at-
502 tributes. The recommendations may not apply directly to all testing applications; however, they
503 should be considered for interoperability and conformance test programs as these practices have
504 proven to be valuable in executing a broad cross-section of program types. Each ITCA should
505 evaluate how these recommendations, observations and practices apply to their specific programs,
506 and incorporate the recommendations into their programs where applicable.

507

508 9.1 General Test Policies

509 ○ Product vendors need to know if their products are eligible for testing and certifica-
510 tion, and how to prepare for certification. In many cases, product vendors may be
511 required to prepare specific test environments (i.e. GUI applications to access low-
512 level APIs, test scripts, supported browsers, dedicated test hardware, samples,
513 etc.) in order to conduct testing of the standard and all underlying software. Ad-
514 vanced knowledge of certification processes helps set expectations of vendors to
515 prepare a product for certification.

516 ○ Final Test Reports should include at a minimum:

- 517 ▪ Test completion dates
- 518 ▪ Test expiration dates as defined by the Certification Body
- 519 ▪ Product name / version / release tested

Interoperability Process Reference Manual (IPRM)

- 520 ▪ Type of tests (i.e. interoperability or conformance)
- 521 ▪ Test script version information
- 522 ▪ Standards version information
- 523 ▪ Technique(s) used for a test including standards and procedures followed
- 524 ▪ Test profile used or a list of test cases if a complete test profile is not used
- 525 ▪ Test equipment used, and all equipment traceability statements.
- 526 ○ Some Certification Bodies have perishable Interoperability Certifications as a best
- 527 practice. Criteria may include expiry dates, and may be dependent on release of
- 528 new standards or products.
- 529 ○ A certified interoperable product shall be conformant to the standard.
- 530 ○ The level of Interoperability and Conformance testing is always a trade-off be-
- 531 tween cost and test coverage. It is highly recommended that the ITCA perform a
- 532 cost-benefit analysis on the degree of coverage associated with the test for both
- 533 conformance and interoperability against the cost to test. In determining the test
- 534 coverage, the security and safety concerns along with appropriate NERC / similar
- 535 requirements should be considered paramount in determining the coverage as-
- 536 sessment.
- 537 ○ Proper test tools produce reliable, repeatable and traceable test results. Such
- 538 tools require validation processes, test suites, tool documentation, test reports,
- 539 calibration certificates and other relevant artifacts. The validation of the test tools
- 540 must be performed against a defined sample of software and / or hardware imple-
- 541 mentations under test. Refer to ISO / IEC 17025 for more detail on the use of
- 542 qualified and calibrated test tools.

9.2 Test Suite Specification (TSS)²

545

Interoperability Process Reference Manual (IPRM)

- 546 ○ A common TSS should be established when one or multiple test labs are deployed
- 547 to test the same standard and / or profile. If unique test procedures are required to
- 548 support a test suite, then they should also be defined.
- 549 ○ The TSS should be test tool agnostic.
- 550 ○ The TSS should be subject to revision control including revision history, revision
- 551 numbering, and a defect / expansion management process. The TSS should
- 552 clearly identify the test purpose, references, resource requirements, test setup,
- 553 procedures, observable results and possible problems / lessons learned with the
- 554 test approach. Observables should clearly identify pass / fail / indeterminate re-
- 555 quirements and informational elements.
- 556 ○ The TSS should clearly define any conventions that will be required to achieve in-
- 557 teroperability.
- 558 ○ The TSS should restrict cardinality and define the exact attributes and associa-
- 559 tions required for interoperability.
- 560 ○ The TSS should remove or clarify all ambiguities and any areas of the standard
- 561 that may be interpreted differently between two or more interoperable systems.
- 562 ○ The TSS should be a standard and managed as such by an SSO. The documen-
- 563 tation should include scope, date of issue, revision, change control, and methods
- 564 to feedback implementer's results.
- 565 ○ The TSS should have accompanying tools to validate data and data structures
- 566 contained in, or produced by, the test.
- 567 ○ Test cases should have clear mappings to feature-sets, use-cases, and require-
- 568 ments.
- 569 ○ The TSS should have a way to feedback the results of the testing back to the pro-
- 570 file.
- 571 ○ The TSS should ensure all areas of the interoperability and conformance testing
- 572 are sufficiently defined and documented such that the test can be repeated.

Interoperability Process Reference Manual (IPRM)

- 573 ○ The TSS should define the test data required to execute the test cases. The TSS
574 should define any test stub required to execute messages that will generate nega-
575 tive responses.
- 576 ○ The TSS should identify interoperability issues arising from ambiguities in the
577 standard, and establish requirements sufficient to prevent those interoperability is-
578 sues.

9.3 Attributes of a Test Profile in lieu of complete TSS

- 579 ○ Must be a subset of the TSS
- 580 ○ Specifies mandatory and optional elements
- 581 ○ Specifies all restrictions
- 582 ○ Cannot add to the standard, but can only restrict the standard
- 583 ○ Define the type of profile (i.e. message, model or implementation) and provide a
584 name for the profile that clearly defines the objective / scope of the profile and the
585 use-cases it is designed to test
- 586 ○ Is a companion standard or is submitted to the SSO for progression as a compan-
587 ion standard
- 588 ○ Is a companion standard or is submitted to the SSO for progression as a compan-
589 ion standard

Interoperability Process Reference Manual (IPRM)

600 11.0 Glossary of Terms

601 **Accrediting Body** – Organization that formally evaluates processes of test laboratories or certifi-
602 cation bodies with respect to specific standard(s) or specification(s).

603 **Application Profile** - A selected subset of the product and / or standard which can be used to im-
604 plement a particular feature set or use case scenario.

605 **Attestation** - Issuance of a statement that fulfillment of specified requirements has been demon-
606 strated.

607 **Certificate** – Unique identifier of a particular product. It applies to both software and hardware
608 products. The certificate can be a physical or digital artifact (e.g., X.509 PKI schemes require digital
609 certificates).

610 **Certification** – Third-party attestation related to products, processes, systems or persons.

611 **Certification Bodies (CBs)** – The entity responsible for certifying that products have fulfilled the
612 requirements of a standard or specification.

613

614 **Compliance Folder** - The set of test evidence, usually including test data, test report, product in-
615 formation, and review records. The folder serves as the record of an implementation fulfilling all
616 requirements of a certification test program.

617

618 **Compliant Portion Description (CPD)** – A CPD is a definitive manifest of all mandatory and op-
619 tional features implemented in a certified product. The CPD is generally used by product designers
620 to judge:

- 621
- 622 • Conformance of an implementation,
 - 623 • Completeness of a system composed of pre-certified sub-components by compar-
624 ing each of the CPDs of those sub-components.
 - 625 • Interoperability of two products based on matching feature sets as described by
626 their respective CPDs.

626 For example, a designer can compare the CPD with the test requirements to determine the level of
627 conformance of a product to a specification. When designing a product composed of pre-certified

Interoperability Process Reference Manual (IPRM)

628 sub-components, the respective CPDs will serve as selection criteria to design the complete prod-
629 uct. The CPD also helps to judge the level of interoperability that can be expected from interac-
630 tions between two independent implementations. A client service and a server function can be re-
631 viewed for their expected level of interoperability solely based on their respective CPDs.

632 **Conformance Certification** – A third-party attestation that a product conforms to a standard or
633 specification.

634 **Conformance Testing** – Determines whether an implementation conforms to the standard as writ-
635 ten. This is done by evaluating the implementation with a test tool such as an emulator, test har-
636 ness, golden unit, etc.

637 **Feature set** – A feature set is a particular characteristic of a product based on a particular use
638 case scenario. For example: signaling price is a feature set.

639 **First Party Testing** – is when an implementer self-tests their own product. This is usually permitted
640 after a technology has matured to where sufficient tools and specifications enabling first party test-
641 ing are available to all vendors.

642 **Inheritance** – Those actions required to evaluate the compatibility of a proposed inherited design
643 including products, subsystem functions and design requirements.

644 **Interoperability** – Ability of a product or system to work with or integrate with another product or
645 system based on defined business requirements.

646 **Interoperability Testing** – Connects two or more implementations together and determines
647 whether they can successfully communicate. Significantly different from conformance testing, it is
648 often possible for two systems that conform to the standard to be unable to communicate. If they
649 can communicate, it is possible that they cannot perform any useful functions. These situations
650 arise because the implementations have conflicting interpretations of the specification, or because
651 they have chosen conflicting options within the standard. A particular form of interoperability test-
652 ing is application testing, in which there is a specification for the particular use of standard that can
653 be tested.

Interoperability Process Reference Manual (IPRM)

- 654 **Implementation Under Test (IUT)** – The implementation subject to testing. Covers System Under
655 Test (SUT) and Device Under Test (DUT)
- 656 **Multi-vendor and Multi-product Testing Event** – An interoperability test of products with other
657 peer products. The outcome of the testing is used to improve both products and the specification.
- 658 **Performance / Protocol / Proforma Implementation Conformance Statement (PICS)** – Defines
659 all mandatory and optional feature sets of a specification that can be used to implement a product.
- 660 **Platform level communications protocol** - In the IPRM, platform level communications protocols
661 are integrated products based on standards only associated with layers 1 and 2 of the OSI layer.
662 (e.g., WiFi platform)
- 663 **Qualified Product Notification (QPN)** – A certificate and accompanying explanatory document
664 issued by the ITCA as a record when a product has fully satisfied the requirements of the testing
665 and certification program. The QPN details all supported feature sets verified by the program.
- 666 **Record of Work** - The material evidence of any work or task, such as test data or test report.
- 667 **Second Party Testing** – Testing activities performed by buyers and users.
- 668 **Security Testing** – Analyzes whether the implementation correctly makes use of any security fea-
669 tures from the standard or other security features available in the product. This is the most difficult
670 type of testing program since it must evaluate whether the system has vulnerabilities, which are not
671 always obvious.
- 672 **Standards Setting Organizations (SSOs)** - An association whose primary activities are develop-
673 ing, coordinating, promulgating, revising, amending, re-issuing, interpreting, or otherwise maintain-
674 ing standards. A Standards Developing Organization is one form of a Standards Setting Organiza-
675 tion. Example SSOs including International Organization for Standardization (ISO), International
676 Electro technical Commission (IEC), Institute of Electrical and Electronics Engineers (IEEE),
677 American National Standards Institute (ANSI), etc. An SSO can also be an industry trade associa-
678 tion that develops industry standards such as the ZigBee Alliance.
- 679 **Static Conformance Review** – A review of designed feature sets versus the specified PICS to
680 determine the extent to which the features are supported by the IUT. This is the first step when a

Interoperability Process Reference Manual (IPRM)

681 product enters a testing program. Generally the test lab requests that the implementer declare all
682 supported feature sets in a product. This information is used to create the test plan for that product.

683 **Testing and Test Control Notation (TTCN)** - A formalized test scripting language used to describe
684 communication protocol test cases per ISO / IEC 9646.

685 **Test Campaign** - A series of tests for a particular product out of the TSS, based on the running
686 Test Profile group and the Test Plan, derived from the Test Case Reference List.

687 **Test Cases** – A set of tests to verify a particular feature set. There are many ways to test a feature
688 set, with each of those representing a test case. Generally, a program defines all possible test
689 cases in the test specification document.

690 **Test Case Reference List** – A current master list of all tests that are to be included into a product
691 test plan. This list also indicates the time variable applicability of each test by reflecting those tests
692 which are no longer valid, and those that are not currently valid but are scheduled to become active
693 in the near future. This helps a product implementer in preparing fully conforming and interoper-
694 able products for an upcoming launch.

695 **Test Harness** - Collection of software, test data, and hardware configured to test a product by op-
696 erating it under varying conditions and monitoring its behavior and output.

697 **Test Interface** - The programmatic application interface to enable communication between a test
698 harness and system or device under test.

699 **Test Plan** – A Test Plan is a list of applicable tests for a specific product and is derived from the
700 Test Case Reference List.

701 **Test Procedure** – A stepwise test method of a particular test case. An example of a test procedure
702 can be the steps needed for an Energy Services Interface (ESI) to send price signals, which may
703 include configuring the time information, updating price tables, etc.

704 **Test Profile or Profile** - A select subset of a product and / or standard to implement a particular
705 test of a feature or a use-case test. Test Profiles evaluate a subset of a TSS and are used to target
706 specific areas of product interoperability.

707 **Test Resource** - Any information, equipment, material, and support required to implement testing.

Interoperability Process Reference Manual (IPRM)

708 **Testing** – According to EN 45020, testing is defined as “the technical operation that consists of the
709 determination of one or more characteristics of a given product, process or service according to a
710 specified procedure”.

711 **Testing Laboratories (TLs)** – Test service providers for a standard or specification.

712 **Test Suite Specification (TSS) or Test Spec-** Consists of a suite of tests, categorized into logical
713 functional areas, such as use cases or well-defined features. Each test suite consists of many re-
714 lated test cases corresponding to a particular feature set or use case. Test cases would include
715 both valid and invalid behavior tests. Each test case is further described step-by-step with test pro-
716 cedures and well defined pass / fail / indeterminate criteria, along with references.

717 **Test Suite-** A collection of related test cases. A test suite can be put together to test a feature set.
718 A pricing test case would be in a “price test suite” but a messaging test case would be in a “mes-
719 saging test suite”.

720 **Third Party Testing** – Testing activities performed by organizations independent of first or second
721 parties.

722 **Use Case** - A description of a system’s behavior as it responds to a request that originates from
723 outside of that system

724

Interoperability Process Reference Manual (IPRM)

725

726

727 **12.0 17025 and ISO Guide 65 Overview**

728 General laboratory and certification body criteria used for accreditation are described in two docu-
729 ments: ISO / IEC 17025, General Requirements for the Competence of Testing and Calibration
730 Laboratories, and ISO Guide 65, General Requirements for Bodies Operating Product Certification
731 Systems. These two documents are widely used across various industries and applicable for Smart
732 Grid testing and certification programs. ISO 17025 is focused on test laboratories and contains
733 requirements that labs need to demonstrate that they operate a management system, are techni-
734 cally competent, and are able to generate technically valid results. It incorporates all requirements
735 of ISO 9001 that are relevant to testing services and facilitates acceptance of test results from ac-
736 credited laboratories. Accreditation bodies apply these requirements in their laboratory assess-
737 ments.

738

739 **12.1 ISO – 17025**

740 ISO 17025 can be applied to any testing lab operation, whether independent (i.e. third-
741 party) laboratories or in-house laboratories operated by manufacturers for their own inter-
742 nal product testing. The advantage of applying ISO 17025 for Smart Grid testing opera-
743 tions is that many labs have already pursued and achieved compliance for selected as-
744 pects of the services they offer, and can simply expand their scope of accreditation to en-
745 compass new services necessary to support Smart Grid interoperability. This approach
746 will build on common best practices used across the testing industry, speeding implemen-
747 tation and avoiding unnecessary creation of redundant processes.

748

749 ISO 17025 focuses on two major areas of laboratory operations: 1) management require-
750 ments and 2) technical requirements. The management requirements address issues such
751 as a lab's documented practices (i.e. both administrative and technical), impartiality of the

Interoperability Process Reference Manual (IPRM)

752 lab in its operations, responsibilities for continuous improvement and issues resolution,
753 and the active support and involvement of lab management in assuring commitment to
754 complying with these criteria.

755
756 The technical requirements focus on areas such as ensuring that lab staff are competent in
757 performing their testing duties, assuring that the lab environment is adequate for services
758 performed, assuring that test plans and other necessary operating instructions are docu-
759 mented and available, and that necessary equipment and software used for testing is cali-
760 brated, maintained and appropriate for its intended usage.

761
762 The criteria described in ISO 17025 is extensive and the brief description above simply
763 provides a high level view of some of the key elements that labs need to address in attain-
764 ing accreditation.

765
766 The technical scope of accreditation is specific to the selected tests / services for which the
767 lab applies for evaluation. Evaluations for compliance can be performed by a number of
768 different accrediting bodies, and there are global and regional agreements in place that
769 provide for broad acceptance of an accreditation once attained.

770

771 **12.2 ISO Guide 65**

772 ISO Guide 65 is focused on certification bodies but parallels many of the same concepts
773 applied to test laboratories. There are general criteria that assure that the organization is
774 non-exclusionary, open and without conflict of interest. Documented administrative poli-
775 cies and processes, as well as documented technical requirements and specifications for
776 certification are among the required criteria. Criteria is also included to assure that proce-
777 dures are in place to describe the granting of certifications, as well as ongoing mainte-
778 nance, extensions and terminations of certifications once granted. Personnel qualifications
779 are addressed for those involved in the evaluation and decision making process associ-

Interoperability Process Reference Manual (IPRM)

780 ated with the organization's certifications. As in the case for ISO 17025, this is only a brief
781 description of highlights associated with the more extensive criteria described in the docu-
782 ment.

783

784 **12.3 Testing Programs**

785 This section is informational only. The goal is to demonstrate how some of the require-
786 ments are being used by various ITCA's. This is not an endorsement of any of the following
787 programs but rather examples to help provide context.

788

789 **12.3.1 Bluetooth SIG**

790 Bluetooth products are low-cost, low powered cable replacement products, primar-
791 ily aimed at low-rate voice / data applications in portable telecommunication prod-
792 ucts. Popular application profiles include hands-free phones, headset, and stereo
793 cable replacements. Bluetooth products are widely known for their interoperability,
794 and billions of products have reached the market.

795

796 The Bluetooth SIG has been operating a testing and certification program for
797 roughly ten years. The design of the program is described in the Program Re-
798 quirements Document (PRD). Throughout the history of the testing and certifica-
799 tion program, a well defined PRD version has been in effect.

800

801 The current Bluetooth SIG PRD calls for physical layer testing with a validated test
802 system at the Bluetooth Qualified Test Facilities (BQTF), and upper layers and pro-
803 file applications are tested by a test harness issued to members by the Bluetooth
804 SIG. The Bluetooth SIG operates as an ITCA for this wireless technology, and has
805 the Bluetooth Qualification Administrator, BOA, as the individual in charge of the
806 PRD administration and interoperability assurance. The BOA and the PRD en-

Interoperability Process Reference Manual (IPRM)

807 sures that the Bluetooth Logo signifies a high-level of interoperability and rich user
808 experience.

809

810 The PRD has defined a testing regime involving various levels of testing, including
811 First, Second, and Third-party testing. The testing is defined in the Test Case Ref-
812 erence List (TCRL), and issued periodically to the industry to define the level of
813 testing depending on the content. For example, the radio layer has been and still
814 is a third-party test, requiring a fully validated test system running a Testing and
815 Test Control Notation (TTCN) radio tester with full test control interface and auto-
816 mated testing. In the past, baseband, link manager and protocol conformance
817 tests were designated as third-party testing, with a specialized protocol confor-
818 mance tester. However, these tests have become implementable by a single
819 common software test system issued by the Bluetooth SIG lead laboratory function
820 since PRD 2.0.

821

822 The BQA chairs the Bluetooth Technical Advisory Board (BTAB), and issues aris-
823 ing in the market are handled by the BQA directly through the BTAB or other cor-
824 rective feedback processes. The Bluetooth SIG maintains a Qualified Product
825 Listing, and issues for each product a Qualified Product Notice (QPN) that defines
826 exactly the conformance and interoperability feature set verified by a static con-
827 formance check of the PICS, and objectively verified with the test harnesses. The
828 BQA oversees verification and auditing process of the BQTF organizations. The
829 BQTF organizations are additionally required to maintain accreditation based on
830 ISO Guide 17025.

831

832 Additional mechanisms include personnel qualifications of Bluetooth Qualification
833 Experts (BQEs), formerly known as Bluetooth Qualification Body's (BQBs). Com-
834 panies are required to maintain a Compliance Folder, detailing the conformance

Interoperability Process Reference Manual (IPRM)

835 and interoperability evaluation record. Products are comprised of smaller Blue-
836 tooth components tested separately, and integrated in a manner that maintains in-
837 teroperability through a Compliant Portion inheritance. The Bluetooth SIG holds
838 regular “UnPlug Fests”, allowing various vendors to test interoperability in a devel-
839 opment environment early in the product and specification lifecycle.

840

841 **12.3.2 WiMAX Forum**

842 WiMAX is a communication technology that enables high-speed wireless data
843 communication backhaul over large distances between fixed base stations, and
844 similar high-speed links from base stations to mobile products. It is also known as
845 a “4G” network, and utilizes the IEEE 802.16e standard for the physical and me-
846 dium access control (MAC) sub-layer. Some AMI networks utilize WiMAX links.

847

848 The WiMAX Forum is an ITCA for the WiMAX standard, and the IEEE 802.16e
849 physical and MAC layer technologies. WiMAX maintains a testing and certification
850 administrator to manage the logo program. A commercial lead lab is operated out
851 of Malaga, Spain. The WiMAX Forum has gone through extensive accreditation
852 processes to select a single testing laboratory in each country, and to provide an
853 economically viable incentive for the labs to participate and facilitate in the growth
854 of the interoperable technology.

855

856 The WiMAX Forum has structured its technology development in stages, and certi-
857 fied products in “waves” synchronized with the product stages. All products are
858 rigorously tested for conformance, regulatory, and interoperability requirements
859 with a validated test set supplied by the lead lab. The test labs participating in the
860 WiMAX certification program are mandated to equip themselves with a validated
861 test system, and manufacturers are encouraged to verify for pre-certification status

Interoperability Process Reference Manual (IPRM)

862 by testing with the same equipment either by themselves or at the accredited labo-
863 ratories. All test cases are clearly defined in a test case reference list, and tests
864 are categorized according to First, Second, and Third-party tests. Logo certifica-
865 tion tests third-party accredited test houses. All accreditation of test houses are
866 performed directly by a team of experts selected by the WiMAX Forum. The Wi-
867 MAX Forum further implements personal qualifications in the form of a WiMAX
868 Qualification Body, who “signs-off” on the test results from the test laboratories.
869 This model provides flexibility to deal with complex interoperability issues. All test
870 labs are required to obtain ISO Guide 17025 accreditation under their respective
871 national auditing schemes defined by their country.

872

873 Manufacturers and test houses are required to maintain a compliance folder that
874 serves as a Record of Work for the logo testing.

875

876 The WiMAX Forum has specified and operated its conformance and interoperabil-
877 ity program as described by their Certification and Interoperability Reference Man-
878 ual.

879

880 **12.3.3 WiFi Alliance**

881 The WiFi Alliance is an industry organization promoting interoperable products util-
882 izing the IEEE 802.11 a / b / g / n physical and MAC layer standards. Initially de-
883 fined as an Ethernet cable replacement technology, it has progressed to include
884 embedded products and mesh networks. Some implementations of Advanced Me-
885 tering Infrastructure (AMI) systems rely on a WiFi-based mesh transport layer for
886 the communication link to the smart meter.

887

Interoperability Process Reference Manual (IPRM)

888 The WiFi Alliance maintains multiple competing laboratories to provide testing ser-
889 vices around the globe. A single lead laboratory is maintained by the WiFi Alliance
890 to develop test cases, evaluate test systems, and in general to be the center of
891 technical competence for the industry regarding conformance and interoperability.
892 An interoperability test harness is defined by and supplied by the Alliance. A certi-
893 fication administrator oversees the program.

894
895 WiFi Alliance laboratories are required to obtain ISO 17025 accreditation, and go
896 through a rigorous auditing process before being selected by the Alliance as a cer-
897 tified laboratory. The WiFi Alliance holds regular test events to help facilitate stan-
898 dard development and interoperability between vendors.

899
900 A product manufacturer can obtain a WiFi logo only after undergoing rigorous test-
901 ing at a WiFi Alliance-selected laboratory, and providing test report evidence to the
902 WiFi Alliance certification administration.

903
904 The WiFi Alliance coordinates with the ZigBee Alliance in support of the Smart En-
905 ergy Profile 2.0 standard for smart grid products in the home.

906

907 **12.3.4 HomePlug Alliance**

908 The HomePlug Alliance is an industry organization promoting interoperable prod-
909 ucts utilizing the IEEE P1901 power-line communication standard. The Alliance
910 maintains several testing laboratories to perform conformance and interoperability
911 testing of the physical / MAC layer based on well-defined test cases and test har-
912 nesses. Several different Phy / MAC layer platforms are supported by the Alliance
913 but not necessarily meant to interoperate across platforms.

914

Interoperability Process Reference Manual (IPRM)

915 The HomePlug Alliance coordinates with the ZigBee Alliance in support of Smart
916 Energy 2.0 standard for smart grid products in the home.

917

918 **12.3.5 ZigBee Alliance**

919 ZigBee Alliance oversees the development of a class of products utilizing Personal
920 Area Network (PAN) technology. Similar to Bluetooth SIG, the ZigBee Alliance
921 handles the interoperability of full application profiles leveraging the IEEE 802.15.4
922 physical / MAC layer standard. This is in contrast to WiMAX and WiFi programs,
923 which are mostly concerned with interoperability of the physical and MAC layer.
924 The ZigBee Alliance handles multiple application profiles, including Telecom Appli-
925 cations, Health Care, Home Automation, Commercial Business Automation, Retail
926 Services, and Smart Energy. The Smart Energy application profile is widely
927 adopted by smart meter vendors and electric utilities as the basis of two-way
928 communication between the smart meter and home-area-network (HAN) products.
929 The Smart Energy application profile is transitioning from 1.x to 2.0, where the sa-
930 lient feature is not only the support of a ZigBee IP layer, but also other IP-based
931 technologies, such as WiFi, HomePlug and others.

932

933 The ZigBee Alliance maintains a few commercial laboratories around the globe,
934 and requires ISO 17025 accreditation and rigorous evaluation of candidate labora-
935 tories. As with other Alliances, each test laboratory is qualified for a particular plat-
936 form or application profile testing after undergoing a peer review process. A certi-
937 fication administrator oversees the logo certification program, and laboratories un-
938 dergo periodic review of performance.

939

940 Test specifications are defined by the industry working groups and “ZigFests” held
941 to verify the viability and interoperability of the technical and test specification with

Interoperability Process Reference Manual (IPRM)

942 participation of the test laboratories. Currently, only third-party testing is allowed in
943 the ZigBee Alliance.

944

945 12.3.6 OPC

946 OPC Self-Testing

947 The OPC Foundation first-party testing program includes a test tool provided by the OPC
948 Foundation which produces a signed and encrypted log file. This log file reports the system
949 configuration, product version and results of the test. It also reports what optional features
950 are supported by the product. This log file can be uploaded to the OPC Foundation website
951 where the signature is verified before it is added to the product catalogue.

952

953 OPC Best Practices

954 OPC is a family of specifications that provide software interoperability in the industrial
955 automation space. The OPC Foundation has been running a certification program for 10
956 years, and has evolved over time based on feedback provided by product vendors and
957 end-users.

958

959 The current certification program has three aspects: 1) self-testing with a tool provided by
960 the OPC Foundation, 2) interoperability workshops where multiple vendors gather and test
961 their products with each other and 3) third-party lab testing. A vendor who completes the
962 self-testing process or participates in an interoperability workshop is eligible to use a 'Self-
963 Tested' logo offered by the OPC Foundation. A vendor that completes lab testing is eligi-
964 ble for a 'Certified' logo. Certifications expire after 2-3 years and vendors are expected to
965 re-certify their products. The OPC Foundation maintains a product catalogue on its web-
966 site that lists all products which have passed the certification process.

967

Interoperability Process Reference Manual (IPRM)

968 The process for developing the certification programs starts during specification develop-
969 ment, where a completely functional reference implementation is completed before the
970 specification is released. This process ensures the specification is implementable. When
971 a specification is nearing completion, a separate compliance committee is formed. The
972 compliance committee creates a test document for the specification, and is used to de-
973 velop the self-testing tool and the lab test procedures. The compliance committee reports
974 any issues that affect testing back to specification committee so the specification can be
975 corrected.

976

977 12.3.7 USGv6 Test Program

978 Overview

979 In the White House Office of Management and Budget (OMB) Memorandum 05-22, NIST
980 is tasked to develop a set of technical requirements for IPv6 for use in the Federal Gov-
981 ernment. In response, NIST published the USG v6 Profile. This document suggests that
982 product testing services are likely needed to ensure the confidence and to protect the in-
983 vestment of early IPv6 adopters. After surveying the existing testing programs, it con-
984 cludes that a distinct United States Government [USG] testing program is needed, but with
985 the commitment to harmonization and convergence in a broad collaborative user / vendor
986 testing initiative, in which the technical and profiling requirements of the USG can be ac-
987 commodated.

988

989 NIST has established the USGv6 testing program as a way to document products' compli-
990 ance with USGv6 requirements. The test program makes use of a set of abstract test
991 specifications, each validated against the respective protocol specifications. To be docu-
992 mented as USGv6-compliant, products must be tested against tools validated to these
993 tests, in accredited laboratories. Having implemented and tested their products, develop-
994 ers must make their claims of USGv6 compliance in a systematic and standardized way.

Interoperability Process Reference Manual (IPRM)

995 The Supplier's Declaration of Conformance (SDOC) is a tool that offers a flexible means of
996 constructing these claims, and will be used to document compliance with USGv6 require-
997 ments.

998
999 USGv6 contains a wide range of elements, and the testing program includes components
1000 that are subject to enhancement and revision over time. Hence it is necessary to have in
1001 place a scheme to manage the evolution and maintenance of these components that in-
1002 cludes collaboration with the stakeholders.

1003

1004 Stakeholders

1005 **"USG Agencies"** have a primary interest in making sure that IT products with IPv6 capa-
1006 bilities are available to meet their acquisition requirements. However, they are typically
1007 more interested in the end product than the testing process.

1008

1009 **"Testing Laboratories"** are central to the USGv6 testing process. Each such laboratory
1010 seeks accreditation from an ISO 17011 compliant, ILAC signatory, accreditation body. Test
1011 laboratories may conduct any of the conformance, interoperability or network protection
1012 testing. First, second and third-party labs are recognized as follows: 1) a first-party lab is
1013 associated with the product developer, 2) a second-party lab is associated with a USG
1014 agency and 3) a third-party lab is independent.

1015

1016 **"Test Method Developers"** include open source suppliers (e.g. Tahi) and private sector
1017 developers, who develop IPv6 test methods for conformance and interoperability based on
1018 the abstract test specifications. In conjunction with test laboratories, test method develop-
1019 ers take part in inter-laboratory comparisons to make sure that test results for the same
1020 test using different methods in different labs are equivalent.

1021

Interoperability Process Reference Manual (IPRM)

1022 **"Accreditors"** - The role of an accreditor is to assess test laboratories for their compliance
1023 with ISO / IEC 17025, which are the quality provisions for testing. They also assess the
1024 technical test methods and technical competence based on NIST SP 500-273.

1025

1026 **"IPv6 Device Developers"** develop hosts, routers and network protection devices which
1027 shall be tested according to the IPv6 criteria when offered for sale to the US government.

1028

1029 **"NIST and the USG test program"** - NIST is a technology agency of the US government
1030 charged with creating a standard for IPv6 devices, and a means of determining compliance
1031 to that standard. NIST SP 500-267 is that standard. NIST SP 500-273, together with NIST
1032 SP 500-281 and this testing program are the means of establishing compliance.

1033

1034 **13.2.7.3 Processes**

1035 Processes associated with USGv6 compliance include testing processes and management
1036 processes. These processes regulate the development of tests, test methods and accred-
1037 ited laboratories. All processes are described below.

1038

1039 **Conformance Testing**

- 1040 • is conducted between the device and / or protocol implementations under test,
1041 and a special purpose test system.
- 1042 • uses tests described in the published abstract test specifications.
- 1043 • must be performed in a first, second or third-party accredited laboratory.
- 1044 • is the gate required before interoperability testing.

1045

1046 **Interoperability Testing**

- 1047 • is conducted among several host or router devices under test.
- 1048 • uses tests described in the published abstract test suites.

Interoperability Process Reference Manual (IPRM)

- 1049
- must be performed in a second or third-party accredited laboratory.
- 1050
- is the prerequisite for issuing SDOC for Host / Routers.

1051

1052

Network Protection Testing

- 1053
- is conducted with special purpose test equipment
- 1054
- uses tests generally described in published abstract test suites
- 1055
- must be performed in a second or third-party accredited laboratory
- 1056
- is the prerequisite for issuing SDOC for network protection devices

1057

1058

SDOC Protection

1059 After testing their devices in an accredited laboratory, product vendors will develop

1060 a Suppliers Declaration of Conformance according to ISO / IEC 17050:2004 that

1061 serves as indication to purchasers that required testing has taken place. Whether

1062 a test laboratory wants to offer the service of SDOC creation after testing is a mat-

1063 ter between the lab and its customer.

1064

1065

Test Methods and Specifications

1066 Test Methods exist for Conformance, Interoperability, and Network Protection test-

1067 ing. For test specifications use the following link:

1068 <http://www.antd.nist.gov/usgv6/test-specifications.html>.

1069

1070

Conformance Test Methods

1071 Any accredited test laboratory can offer the conformance test methods, including

1072 first, second or third-party test labs. Conformance test methods are located at

1073 <http://www.antd.nist.gov/usgv6/test-meth-c.html>.

1074

1075

Interoperability Test Methods

Interoperability Process Reference Manual (IPRM)

1076 A seemingly intuitive way to do interoperability testing is on a device-by-device ba-
1077 sis. However in practice, the range of configurable options in the USGv6 profile is
1078 so flexible that in the end it is better to construct interoperability test suites per Re-
1079 quest-for-Comment (RFC) and run the required set of tests according to each de-
1080 vice's configuration. For this reason, the interoperability test methods are struc-
1081 tured identically with the conformance test methods. The test suites associated
1082 with these methods are uniquely applicable to interoperability testing. Interopera-
1083 bility test methods can be found at [http://www.antd.nist.gov/usgv6/test-meth-
1084 c.html#interop](http://www.antd.nist.gov/usgv6/test-meth-c.html#interop).

1085

1086 **Network Protection Test Methods**

1087 Network protection test methods cover firewall, application firewall and intrusion
1088 detection systems, and may be tested by a second or third-party test lab. Network
1089 Protection Test methods can be found at [http://www.antd.nist.gov/usgv6/test-
1090 meth-c.html#npd](http://www.antd.nist.gov/usgv6/test-meth-c.html#npd).

1091

1092 **Supplier's Declaration of Conformance**

1093 Suppliers test Host, Router or NPD products in accredited test laboratories. Test-
1094 ing of different capabilities can occur in different test labs. Each test event and its
1095 date are recorded in the Supplier's Declaration of Conformance (SDOC). Capa-
1096 bilities implemented and tested should be correlated with the test methods listed at
1097 this site. An SDOC template in Excel format is provided to allow for summariza-
1098 tion of the testing done. The second sheet of this Excel file is the USGv6 version
1099 1 capabilities checklist, indicating what functions must be supported.

1105

1106 **IPv6 Forum - IPv6 Ready Logo Program**

1107 The IPv6 Forum (<http://www.ipv6ready.com>) IPv6 Ready Logo Program is a con-
1108 formance and interoperability testing program intended to increase user confi-
1109 dence by demonstrating that IPv6 is available now and is ready to be used.

1110

1111 The IPv6 Ready Logo Committee mission is to define the test specifications for
1112 IPv6 conformance and interoperability testing, to provide access to self-test tools
1113 and to deliver the IPv6 Ready Logo. The Key objectives and benefits of the IPv6
1114 Ready Logo Program are to:

1115

- 1116 • Verify protocol implementation and validate interoperability of IPv6 prod-
1117 ucts.
- 1118 • Provide access to free self-testing tools.
- 1119 • Provide IPv6 Ready Logo testing laboratories across the globe dedicated
1120 to provide testing assistance or services.

1121

1122 **Process**

1123 The process requires vendors to pass 100% for both conformance and in-
1124 teroperability test specifications. Interoperability requires testing with four
1125 different interoperable vendor devices.

1126

1127 Allows vendors to either use self-test tools or utilize test laboratory ser-
1128 vices. No accreditation is required.

1129

Interoperability Process Reference Manual (IPRM)

1130 Once the vendors have applied for the Logo, the IPv6 Ready Logo Com-
1131 mittee has an administrative process to review and verify the test results.
1132 Once approved, the vendor will be added to the Approved List.
1133 <https://www.ipv6ready.org/db/index.php/public/>

1134

1135 **12.3.8 System testing**

1136 System-wide, end-to-end interoperability testing is crucial to build an ecosystem of inter-
1137 operating vendor products. As such, the following example has proven to be effective to
1138 ensure system wide testing.

1139

1140 **Texas Go-To-Market ZigFest**

1141 The joint Texas T&D utilities and the ZigBee Alliance has sponsored multiple
1142 events to test an end-to-end provisioning and signaling system that connects
1143 Smart Meters to HAN products. This has allowed finer interpretation and business
1144 use case verification and interoperability with multiple vendor implementations of
1145 specified application profiles.
